The acetozone treatment has also been used in a case of syphilitic *neuro-retinitis* that progressed rapidly in spite of pil. hyd. c. creta, II. t.d. The disease was promptly arrested, the discs became normal, and vision $\frac{6}{6}$ easily in six weeks. The results in all forms of iritis were admirable and equally so in interstitial keratitis when seen within a week or so of the commencement of the disease. Indeed, in the latter two or three days at times suffice to remove the corneal opacity and nothing remains but a little keratitis punctata. In future cases there is no reason why the treatment should not be combined with inunction but in nearly all the cases treated by acetozone mercury has been tried for at least six weeks and in some cases for several months. The only objection to acetozone is the price and this is a consideration if the drug has to be used for several weeks. Doubtless in iritis this would be inconsiderable and the money wisely spent. Three-grain doses have excellent results but it is not unlikely larger doses could be given with advantage. The use of the drug by means of capsules may have its drawbacks, but this method has advantages, and in eye diseases there is not the objection to the exhibition of the remedy in solid form which might be offered in the case of enteric disease. However administered there is no doubt it should be given in eye cases with a much larger quantity of water than in typhoid fever. The limitations as to space prevent my taking up the bacteriology of the subject but I propose to deal with this on another occasion.

I am, Sirs, yours faithfully,

CHARLES WRAY, F.R.C.S. Eng.,
Surgeon, Western Ophthalmic Hospital; Ophthalmic
Surgeon, Croydon General Hospital and
Croydon Infirmary.

COEXISTENCE OF DISEASES.

To the Editors of THE LANCET.

SIRS,—I read with much interest your annotation on the Coexistence of Diseases in THE LANCET of August 25th, p. 515. In it the following sentence occurs: "The result of an infectious disease occurring in a tuberculous subject does not essentially differ from that found when a healthy subject is attacked except that in the former the powers of resistance are less and not infrequently an intercurrent affection is so badly borne as to threaten seriously the patient's life." That recalled to my memory a case that came under my notice some three years ago in which scarlet fever, (Rifle): 1st Volunteer Battalion the Northumberland Fusiliers, Surgeon-Major and Honorary Surgeon-Lieutenant-Colonel Duncan Stewart. Eastern Command (Artillery): 1st Cinque Ports Royal Garrison Artillery (Volunteers), Surgeon-Major James William Thornton Gilbert.

In view of the approaching despatch of a draft of Royal Artillery to India, an order was recently issued at Woolwich that officers should ascertain the names of men, women, and children willing to be inoculated against enteric fever. Notwithstanding Lord Kitchener's recent remarks on the subject at Simla, the only volunteer was one man of the veterinary department.

The War Office has under experiment a number of ruck sacks—a bag of the Austrian type—which have been submitted to certain committees as a suitable method for the soldier to carry his belongings on service, as well as to replace the valise, which is now practically abolished in the British army.

The finger-print system is to be adopted in the United States Army as a means of identification of soldiers.

Correspondence.

"Audi alteram partem."

ON THE CORRECTION OF DEATH-RATES.

To the Editors of THE LANCET.

SIRS,—In Dr. T. F. Pearse's article on the "Correction of Death-rates," assuming the accuracy of his arithmetical calculations, he correctly sums up their result when he points out that the death-rate in Calcutta in 1904, calculated at the age and sex rates of mortality prevailing generally in Bengal, would be equal to 36·6 per 1000, whereas the death-rate of the Bengal population calculated at the age and sex rates of mortality prevailing in Calcutta would be equal to 38·7 per 1000. It is, however, impossible to agree with Dr. Pearse when he asserts that the difference between these two corrected rates proves the insufficiency of the method adopted by the Registrar-General for the correction of the crude recorded death-rate in a town or district for abnormality of the age and sex constitution of the population. It is obvious that in the case dealt with the Registrar-General's method shows what the death-rate in the Calcutta population in 1904 would have been if the sex and age rates of mortality had been the same as those that prevailed in the standard population of Bengal. The alternative method, on the other hand, shows what the death-rate in the Bengal population would have been in 1904 if the sex- and age-rates of mortality had been the same as those that prevailed in the population of Calcutta. Could Dr. Pearse have expected that these two entirely distinct calculations would have yielded identical results? As a matter of fact, this alternative method is adopted by the Registrar-General in his Decennial Supplement, but could not be used for his Annual Summary. Incidentally, the startling excess of the female rates of mortality recorded in Calcutta in 1904, shown in Dr. Pearse's Table A, suggests the probability either of a considerable under-statement of the female population of that city at the census in 1901, or of its rapid increase between 1901 and 1904, or of some other error in the recorded facts, since the Bengal female death-rates, given in his Table B, are considerably below the male death rates, as is almost invariably the case in all trustworthy mortality statistics.

I am, Sirs, yours faithfully,
NOEL A. HUMPHREYS.

Surbiton, August 27th, 1906.

To the Editors of THE LANCET.

SIRS,—The method of calculating corrected death-rates described by Dr. T. F. Pearse in THE LANCET of August 25th, 1906, p. 500, is practically the same as that given by Dr. T. W. Hime in his "Practical Guide to the Public Health Acts," second edition, 1901, pp. 544–548. Dr. Hime in a footnote observes that his results for Bradford differ very materially from those of the Registrar-General (23·38 as against 21·31 for males) and that the results of the latter are "wrong." In the case of Bradford, therefore, not a very abnormally constituted population, as in the case of Calcutta, the application of this method leads to a corrected death-rate considerably higher than that obtained by the Registrar-General's method. There are, as Dr. Pearse notes, two methods of making the required correction. The Registrar-General applies the mortality-rates adopted as a standard to the various age and sex groups of the population under consideration; while the other method applies the mortality-rates obtaining in the population in question to a standard population. The latter is the method preferred by Dr. Pearse and by Dr. Hime. Its use is negatived in very many instances by the fact that mortality rates in sufficient detail are not obtainable for the populations under consideration, whereas the age and sex constitution of all important populations is to be found in the census reports.

Dr. Hime, in his application of method No. 2, adopts as his standard population a "standard million," constituted as was the population of England and Wales at the preceding census; Dr. Pearse uses a "miniature population" of 847,796, the census population of Calcutta, constituted as was that of Bengal at the preceding census. The result obtained would have been exactly the same in each case had the total census populations of England and Wales and of Bengal respectively been utilised. If this had been done in the case of Calcutta, for instance, the various age-and-sex group populations in Table D of Dr. Pearse's article would have been increased in equal proportion (847,796 : 70,000,000, or, population of Calcutta : population of Bengal) and the calculated deaths in the same table would have been increased in the same proportion. Consequently the calculated death-rate obtained would not have been affected. The same thing may be shown in the same way for Dr. Hime's method, whence the practical identity of the two is obvious.

If, then, apart from mere variations in detail of application there are two principal methods by which corrected death-rates may be calculated, both apparently at first sight satisfactory in principle but yielding discrepant results, an important question arises as to which is to be preferred and why? This matter is, however, beyond the scope of the present letter and, as pointed out above, practical considerations will generally restrict the statistician to the method of the Registrar-General.

I am, Sirs, yours faithfully,
T. H. C. STEVENSON.

August 31st, 1906.

THE ROYAL BERKSHIRE HOSPITAL.

To the Editors of THE LANCET.

SIRS,—Some few years ago I was appointed physician to the Royal Berkshire Hospital under the following rule: "No person shall be eligible for the office of physician to the hospital unless he be a medical graduate of one of the universities of Great Britain or Ireland and his name entered on the Medical Register; neither shall any person be eligible who practises or is connected in partnership with anyone practising surgery, pharmacy, or midwifery." Recently this rule was altered to the extent that the practice of midwifery was to be allowed if desired. At the same time it was decided that two assistant physicians should be elected who were to have beds allotted to them and to have charge of the out-patient department and a physician was to be elected to form a skin department. This matter was never brought before the staff as a whole, neither were the physicians asked if they were prepared to give up beds or to give up their out-patients. At the election of the assistant physicians neither of the two conformed to the mode of practice demanded for the physicians and subsequently a rule was passed to meet their mode of practice, and at the same time they retain beds and have charge of the out-patient department, and one takes charge of a skin department so that by no chance does a physician have a skin case under his care.

I should be glad to have your opinion whether the physicians have been fairly treated in this matter and whether the governors are acting within their rights in taking away from the physicians the rights and privileges under which they came to take up the appointment in Reading.

I am, Sirs, yours faithfully,
FRANCIS HAWKINS.

Reading, August 1st, 1906.

⁂ An officer elected under one set of regulations has a distinct grievance if during his term of office the regulations are changed so as to affect his position. So far we are with Dr. Hawkins. But if in the opinion of the authorities the change is in the nature of a reform (i.e., if the authorities previous hour or two usually yields valuable evidence, while surveillance for an hour or so after the official examination is advisable. On two occasions I have negatived the charge of intoxication by proving the accused to be suffering from locomotor ataxy; in one of these cases the introduction of the patient into a well-lighted room had the effect of steadying his staggering gait. An examination of the eyes sometimes reveals a cause for obliquity: the discovery of night blindness accounted for the vagaries of one individual; the existence of previously undiscovered hypermetropic astigmatism dispelled a charge of carelessness in another. Again, while waiting about at the Guildhall I was called on to give medical evidence; the defendant, a van driver, squinted. I stated that he was most likely one-eyed. Investigation on the spot proved that to be the condition and influenced the verdict.

It is in sexual or obstetric cases that we meet with most of our problems. Questions are often asked as to pregnancy, paternity, &c., without any forensic involvement which, however, have a medico-legal interest. Once I was interviewed by an irate matron who produced her husband's blood-stained shirt, some black hairs collected from his coat sleeve, and from his coat pocket the unused half of a first-class return ticket to a well-known suburban resort. The lady argued from the position of the bloodstains that they were not from "his" person but "hers," and could I state if the stains were menstrual blood. I said that there was no proved distinction. The circumstantial evidence plus the *pieces de conviction* showed that the lady had a grievance, but I considered my friendly offices were better employed in pointing out difficulties of evidence and advising her to ignore for the present the presumption of guilt. Thrice I have been asked to examine girls with reference to virginity. In one case, where there was no specific charge, I refused to examine the young woman, pointing out that the result was nearly as likely to be negative as positive, and in the absence of a direct charge she was running the risk of an uncertain verdict which she was not compelled to do. The second case was that of a half-witted girl, aged 14½ years (now in a lunatic asylum), on whom a man was charged with rape; as she had apparently been a consenting party no marks of violence were visible, the lax and distensible hymen was untorn and the vagina dilated. I considered penetration possible but found no local evidence of force. Subsequent evidence proved that the girl was unchaste. The third case was that of a girl, aged 15½ years, whose bedroom a man was seen leaving; actual connexion was denied, and the girl objected to examination. I pointed out to the parents that she could not be compelled to submit, and that if I examined her it must not only be in the presence of witnesses but by her consent and in this case at her request. Result, *virgo intacta.* Circumstances requiring it, I once examined per vaginam a *virgo intacta*, aged 21 years, and found the os and cervix uteri deeply notched on one side; the condition was undoubtedly congenital but might have been taken for an injury resulting from delivery and led to the hypothesis of past maternity.

In some districts abortions and miscarriages are frequent and mostly occur without medical attendance, for the prevention of conception or the annulling the result are processes which appear to be now so well understood and so widely practised that application is not probably made so frequently in these days to the doctor to effect the process as formerly. Most of us have been asked to procure abortion. Such a request has been made to me on two or three occasions, and on each I have without undue delay confided the circumstance in all its details to some professional friend, whom I have requested to note in writing the case, that in the event of abortion occurring in my applicant, and accident or scandal accompanying it, I might be able, if necessary, to refute a charge of complicity. Several times while attending a miscarriage I have found small empty bottles labelled "pennyroyal" stowed away out of sight behind larger objects on mantle-shelf, chest, or dressing-table, and more than once has the patient confessed to the means she had adopted to cut short gestation.

Some months ago I was called to attend a woman whom I found very ill with uterine hæmorrhage and abdominal pain. She told me that during the previous week she had "lost a lot" and had probably miscarried. I found her to be suffering from an incomplete abortion and lead poisoning. She recovered after a long and serious illness and confessed that finding herself pregnant she began about the seventh or eighth week to take daily as much sugar of lead as would lie on a sixpence. She aborted at about three and a half months. In a case where I diagnosed internal hæmorrhage the woman was taken suddenly ill with very severe abdominal pain and died in a few hours. I found an empty bottle of "pennyroyal" and was told by the husband that the deceased believed herself to be pregnant again. By permission I, with the help of a brother surgeon, made a post-mortem examination and found a large quantity of blood in the peritoneum which had come from a burst vein in the left Fallopian tube. The patient was not pregnant and we could not find any evidence of an extra-uterine pregnancy. The case reminded me of the death of Miss Adelaide Neilson; she had an attack of gastralgia while driving in the Bois de Boulogne and died 12 hours later from syncope. Dr. Brouardel made a post mortem and "disclosed the extraordinary fact, one of the rarest in the history of medicine, that in her writhing she had ruptured a varicose vein in the left Fallopian tube, and had died of hæmorrhage." (Letter in *Times*, August, 1880.) Query, may not the hæmorrhage have caused the writhing?

That an experienced matron may erroneously believe herself to be pregnant hardly requires illustration. Mrs. S., the mother of several, engaged me to attend her one December. She sent for me in time. I found her in bed, with nurse, &c., in attendance and all in readiness; pains occasional. On examination I found her not to be pregnant, much less in labour, told her to rise and dismiss the nurse, and I prescribed for the stomach-ache. Two months later I was summoned to her again, this time for a miscarriage at about three months. Consequently she must have been about six or seven weeks advanced on the first occasion. On the other hand, pregnancy may exist without the cognisance of the woman; examples are plentiful. My first experience was years ago with a woman, aged about 44 years, who had been married 20 years without ever being pregnant. She sent one evening on account of severe stomach-ache and was much surprised on being informed that she was in labour. She was safely delivered with the aid of forceps. Suspicion and incredulity are naturally excited when an unmarried woman denies an existing pregnancy. Once I had a young woman persist in her denial even after delivery! But I think that ignorance may rarely be genuine. A "simple" and single woman, aged 35 years, living as one of a large family of brothers and sisters, fell in labour one evening. No suspicion of her condition existed. I was sent for to treat colic. I "looked" my diagnosis at her step mother, a matron of knowledge, only to be answered by pained disbelief. I am quite sure the patient herself did not realise the truth, until after a short, easy labour, she remarked: "It is a baby, then, after all." Paternity was admitted by the infant's father, who had gone abroad months before, after one intimacy. A call in the middle of one night fetched me to a confinement where I found the mother on the floor, and the baby, a fine boy, head downwards in a chamber-pot with water up to the brim. This was a fourth child, and two experienced matrons were present at birth, yet so frightened were they all that no attempt was made to save the child, though, as I pointed out, to knock the vessel over on to its side would have been sufficient. The infant was dead—drowned because of the nervous horror of those present. Had the patient been unmarried, and confined when alone, the circumstances might have excused the suspicion of infanticide, yet evidently the accident was possible.

Twice or thrice I have been called upon to decide before burial if the corpse were dead; in every case the body was that of a child and the presence of incipient putrefaction, in one case a fine greenish line along the free edges of the eyelids, left one in no doubt. These cases all occurred in cold weather, and the calm of the features with a tendency to rosiness of the face caused the doubt of the friends as to death.

A fine young man after shooting his employer (not fatal) shot himself. I opened his head and found the wound of entrance on the left temple a little above and in front of the left ear; the bullet traversed the brain and was found lodged against the inner table of the skull at a point somewhat behind and above the right ear. I gave it as my opinion that the deceased must have been left-handed; a relative was recalled by the coroner and stated that he was.

A middle-aged woman cut her throat with a razor one Saturday. I was fetched from a cricket-match three miles away. No one had touched her. She lay in a large pool of clotted blood on the floor of her cottage. I found her just living. The wound was four inches long and longitudinal in occurring as an intercurrent affection in a patient suffering from tuberculous disease of the hip-joint, *appeared to have* a beneficial and curative influence on the tuberculous condition.

A boy, aged seven years, was under treatment for tuberculous hip disease with a sinus discharging on the postero-external aspect of the thigh when he had an attack of scarlet fever. He was removed to the isolation hospital. A large abscess had now formed on the anterior aspect of the thigh in the region of the hip and *it was necessary to* operate. Under an anæsthetic the abscess was incised and a gauze drain was put in. For the next two or three days the boy lay in a very precarious condition and it was doubtful if he would recover. However, the fever abated and he began to improve. As convalescence progressed the tuberculous condition got very much better and by the time convalescence was established the tuberculous sinuses had healed. The change in his general condition was also very marked. At first he was thin and pale, but during convalescence he put on weight and when discharged was quite *fat and rosy. He was also able to run about* and had no discharging sinuses, a state of affairs which had not been his for over two years.

The question is whether the cure of the tuberculous condi*tion was influenced by the scarlet fever. I have not had an* opportunity of watching another case similar to the above. Of course, there is always the chance of the cure occurring at that time being a mere coincidence, but I must say I have never yet seen a tuberculous condition take such a rapid turn for the better.—I am, Sirs, yours faithfully,

August 25th, 1906. John Allan, M.B.

HÆMATOGENOUS ALBUMINURIA.

To the Editors of The Lancet.

Sirs,—I was interested to read Dr. E. Hingston Fox's article on this subject in The Lancet of August 25th, p. 497. Since the publication of Sir A. E. Wright's observation on the influence of calcium lactate in so-called "functional" albuminuria I have tested the point repeatedly. In four cases which I suspected to be of this type the albuminuria was readily controlled by the drug, but in cases with other evidence of kidney disease calcium lactate had no obvious effect. I therefore agree with Dr. Fox that it is a useful diagnostic test and that the primary cause of the albuminuria is the state of the blood. But I am inclined to think that he rather belittles the disturbance of the cardio-vascular mechanism in these cases. The great tendency to fainting, especially on standing for some time, and the appearance of albuminuria only after getting up, strongly suggest a lax condition of the vaso-motor system which, failing to compensate for the effect of gravity, allows both cerebral anæmia and back pressure on the kidney to occur. These considerations have led me to use digitalis as well as calcium lactate and, so far as I can judge, the effect has been good.—I am, Sirs, yours faithfully,

W. Langdon Brown.

Finsbury-square, E.C., Sept. 3rd, 1906.

THE GERMAN LANGUAGE AND MEDICAL MEN.

To the Editors of The Lancet.

Sirs,—I have received several letters from your readers which indicate that there is some difficulty in obtaining Messrs. Fiedler and Sandbach's little book. With your permission I will give the specification for order through a printer: "A First German Course for Science Students," by *H. G. Fiedler and F. E. Sandbach.* Alex. Moring, Limited, the De la More Press, 32, George-street, Hanover-square. 1906. 2*s.* 6*d.* net. I am, Sirs, yours faithfully,

Arthur Loxton.

Sept. 3rd, 1906.

SANITATION AT ST. MORITZ.

To the Editors of The Lancet.

Sirs,—In answer to an inquiry by Dr. T. W. Parkinson on this subject[1] there appeared in The Lancet on Sept. 16th, 1905, p. 854, a letter signed by Dr. J. F. Holland and Dr. P. Gredig which stated with regard to the winter season 1904–05 as follows: (1) that the main drainage was sound; *(2) that the public health* was in no way endangered; and (3) that the chief main drainage was then carried right out into the river Inn, whence it issued with torrential force.

The wish was no doubt father to the thought. It seems, however, on inquiry, (1) that the experts referred to in the letter had (as the authorities *frankly admit*) *recommended* that all drainage into the lake should be stopped and another system adopted, thereby showing that in their opinion the existing main system was faulty; (2) that complaints of suppurative tonsillitis and like ailments were extraordinarily numerous during the winter in question, and when septic illness occurs in an antiseptic air and the drains are subsequently ordered to be remodeled it is more likely that the public health was endangered than not, though actual typhoid fever, diphtheria, &c., were absent; and (3) that (as the authorities likewise admit) the new main system instead of *being complete on Sept. 16th, 1905, as stated in the letter,* was not complete in March, 1906, or expected to be so till later.

The fact is that St. Moritz had rapidly outgrown its sanitary system, and though the authorities assure us that they are doing their best to put things right the publication of a certificate by first-class independent professional experts *that the entire system, both* main and subsidiary, is now *perfected and up-to-date* would be more conclusive than any other assurance. At present the only promise obtainable (in March last) is that the work when complete will be certified by an authority, but by whom and whether or where the certificate will be published is not stated nor whether it will include the subsidiary system.

I trust I have said enough to show that there is nothing unreasonable in now asking for the publication of this certificate in The Lancet, especially as it is over a year since the London Sanitary Protection Association reported confidentially on the matter and suggested the necessary alterations. Such a step would at once remove the uneasiness to which Dr. Parkinson referred, and would be in the best interests of the place to which many of us owe much.

I am, Sirs, yours faithfully,

H. Campbell Jenkins.

United University Club, London, Sept. 3rd, 1906.

THE MEDICO-LEGAL EXPERIENCES OF A GENERAL PRACTITIONER.

To the Editors of The Lancet.

Sirs,—Though he gets it up for examination purposes the average general practitioner has but few important opportunities during even a long life of work of exercising his medico-legal knowledge. Even if a great or important incident *does come in his way the introduction* of an "expert" deprives him of much of any credit or glory obtainable. To most of us our medico-legal experiences *consist* of an occasional inquest which, in the majority *of cases, presents* no difficulty, medical or legal, and does not require the employment of the coroner's pet pathologist; an occasional lunacy certifying, which does often present some difficulty; and more rarely a police-court case—viz., assault, &c. Nevertheless, though great occasions are exceptional, minor incidents are not so infrequent in which interesting *medico-*legal points are involved.

At some time or another nearly every one of us must have been called upon to decide as to the sobriety or otherwise of a given individual, and much may depend on our verdict. The difficulty of *decision* is often very great and the gradations between "*dead drunk*" and "had been drinking but was not drunk" are many and subtle. Even the interval between the apprehen*sion of* the accused and the appearance of the doctor may have been sufficient to allow of the disappearance or modification of the signs of intoxication. The accused may lighten one's *task* by admitting to a glass or two, or *to* having "mixed." The most should be made of such admissions before imposing all those tests of sobriety *familiar* to the police, for it is possible for the man who has exceeded to pull himself together and neutralise the evidences of alcoholic excess and evade the pitfalls contained in polysyllabic alliterative lingual trials. In all cases the medical examiner should conduct his examination before *witnesses,* and *fortify* and support his opinion by the *testimony* of others whose *sobriety* should be undoubted. An inquiry into the history of the an appointment as an additional medical officer in my special department at our children's hospital. But my advances in this direction were met with chilling disapproval by the members of the hospital staff. I was speedily made to realise the strength of that barrier wall which is created by provincial hospital men as an exclusionary measure against other medical practitioners residing in the same town. Preventive and hygienic work amongst the children in the schools next offered attractions to me as seeming to afford scope for the energising of my somewhat restless spirit. I was abetted in this by the fact that the medical officer to the education committee was not particularly interested in eye, ear, and throat work. I therefore suggested collaboration with him in this special department, and even framed an elaborate scheme of special medical school inspection which, I believe, was not devoid of some redeeming features. Once again did vigorous opposition confront me. I was informed by one and caucus that I, a general practitioner, had ethically no right to assume possession of any special knowledge and experience superior to that of any other general practitioner. This trades union spirit animated the forces fighting against me and—triumphed. My next step was to organise a dispensary for children and diseases of the eye, ear, and throat, of a special, semi-gratuitous, self-supporting character. On discussing my little scheme with a London ophthalmic surgeon recently I was informed that its analogue can be seen in different continental cliniques, notably that of Dr. Darier of Paris, who was unprovided with a hospital appointment and devised his clinique to meet this want. My scheme went further. It was an honest attempt to solve certain medico-social problems. My medical brethren are attacking my dispensary work by deploying against it a system of covert slander which is more effective than open attack, for I am powerless to combat it. A little later I opened special consulting rooms in our professional square and on a brass plate advertised the fact that I attended at certain hours on certain days for special consultations on diseases of the eye, ear, and throat. This year in Ostend I saw to my joy similarly announced by a medical man consultations for *maladies des enfants*. With great interest I read in the letter of "S. H.' of the common custom in Germany and Austria of such door-plate indications. I also notified my patients of my new departure in professional work by means of a printed card and a notice on my bill-heads. For I had to work to live!

---

[1] The Lancet, August 14th, 1905, p. 553.

These advertising methods have been deemed to be so atrocious that not one medical man has introduced a special case to me at the "Square," or has asked me to meet him in special consultation. My colleagues do not even trouble to reply to my letters respecting their patients who persist in consulting me. Whilst remaining personally friendly with one and all, professionally I am subjected to a boycott which daily menaces me in my practice. I thought to soften the hearts of my opponents by writing a little book which you, Sirs, kindly noticed in a recent number. I find, however, that the local medical men will not buy a copy even at 1*s.* net.

In conclusion, I contend that I have a legitimate right thus to push my "specialität," although a "practischer arzt," and that it is degrading to the profession for medical men to encourage, as they do, advertising opticians and hospital abuse, while ostracising members of their own profession. I write my pioneer experiences—*pour encourager les autres.*

I am, Sirs, yours faithfully,

August 27th, 1906. M.D., B.S. LOND., D.P.H. CAMB., &C.

To the Editors of THE LANCET.

SIRS,—I am but a comparatively young member of the profession and, no doubt, ignorant of much which may ere long cause me to modify the opinions of which I am at present possessed. I am, however, for the moment bound to aver that your correspondents appear to me to approach this subject from a point of view which is ethically incorrect. I have been connected for the past few years with a special hospital and have devoted a considerable amount of time to the class of disease which is there treated and, supposing that I have brought to bear upon that subject a fair amount of intelligence, may perhaps lay claim to some special knowledge of it. So far, however, as my own feelings are concerned I would not dare to call myself a specialist. I look forward to the time when the public shall regard me as a specialist and when my professional brethren shall know me as one, but to assume the appellation seems to me beyond my just right. The impression I have derived from my masters in medicine is that no one of them would like to call himself a specialist, though each one would like to be in possession of special knowledge of some particular branch of our science and art. It is at any rate a view with which I am content.

But the strongest argument which can be advanced against the assumption of the term specialist may be advanced from the side of the public. A man in want of a doctor seeing a brass plate with a name and a description of "physician and surgeon," or some equivalent, upon it, knows that within is one whom he may expect to have a reasonable amount of medical knowledge, at least as reasonable as medical authoritative bodies can make it. What is a member of the public to know when he sees the appellation of specialist upon a plate? It may be that the man within really has some special knowledge, or it may only be that he thinks he has, or it may be that he desires to give the public the idea that he has it, though in fact he has it not. In any event the man is applying to himself an adjective which no authoritative body vouches for.

I am, Sirs, yours faithfully,

August 29th, 1906. X.

To the Editors of THE LANCET.

SIRS,—It seems to me that the days are past when a man might make up his mind at the outset, or soon after, which branch of our profession he is going to adopt. Certainly this is true with respect to surgery. Let it be granted that a man at the beginning of his career says, "I wish to be a surgeon. I shall so far as possible arrange my work with that end in view. I am not a grasping man and I do not want a plum. I merely wish ultimately to practise surgery as distinct from medicine and I hope I shall be granted facilities for starting in that direction. I am willing to devote so much time to it and to lay out so much capital. Both are above the average amounts." I maintain that, however well such a man may carry out his intentions, however well he may ground himself, and however conscientious and perhaps clever he may be, he is in infinitely greater degree the victim of chance. For instance, it is in the first place, judging from the numbers published, at least two to one against his passing the primary Fellowship examination of the Royal College of Surgeons of England, an examination in two subjects each of which is far too vast for anyone to know the whole of it at once and in which there is no defined schedule. In each only about one tenth of the knowledge is of practical value, the rest is, as a matter of fact, soon forgotten to make room for useful matter. Any particular point in either can be, and is, at once easily revised for purposes of research or for operative procedure. It is said that one can make a certainty of passing this examination and that the best men get through. The first of these statements is quite inaccurate. At any one attempt the element of chance is utterly demoralising. The second statement is in the main true, though numbers pass who never deserve to and numbers fail who would make far better surgeons than many who pass. Many who pass become surgeons simply by reason of having passed, and, indeed, have never from the outset laid down for themselves any plans at all.

In the second place it is at least a two-to-one chance against our man in the final examination. So that only one-ninth of those who enter for the Fellowship of the Royal College of Surgeons of England obtain it. The result time and again is a great loss to the medical profession and to the country, because the requisite qualities of a surgeon cannot be determined finally and wholly by any sort or kind of examination. They might be found out by the apprenticeship system and if the results of original research work were taken into account. At present the quick-witted man with a good temporary memory, who can write quickly, though without a grasp of principles, may happen at the time to be thinking in the same way as the examiner, may pass, while a systematic, plodding man will fail. I maintain that among this eight-ninths of those who desire to become Fellows of the Royal College of Surgeons of England are many who have failed not because they showed themselves incompetent to make good surgeons but because the tests are not properly devised. Failing in examinations there is no alternative proceeding and they are driven to take position, running parallel to the right side of the larynx and trachea. The great vessels had escaped injury and she recovered after some weeks. She was watched by her relatives for some time, but giving no trouble surveillance ceased. Exactly one year after her first attempt, again on a Saturday, she successfully committed suicide by drowning in a shallow well, being found head downwards with the lid resting on her ankles.

It is astonishing what a healthy lot proposers for life insurance almost invariably say they are. Deliberate suppression of the truth or falsification is probably the exception, but unconscious bias in his own favour is, after all, only natural in the account given of his past health by an examinee. I always inquire of a proposer if he belongs to any benefit society or sick fund, and follow this up by asking how long he has been a member; then a tender inquiry if he has ever been on the funds and, if so, how often and for how long a time, and what for, usually brings to recollection some forgotten illness or indisposition. Quite frequently an individual will deny ever having suffered from rheumatism, but admits that he has had "growing pains." In these days of conscientious objectors and cranks it is as well to take note of vaccination. Insurance companies will probably find it necessary to revise their premiums in the case of the non-vaccinated, for that class is increasing all over the kingdom.

Recent legislation may bring the general practitioner more often into the law courts. The Workmen's Compensation Act offers chances which the malingerer does not neglect. We all know how fatal to fortitude is the fact that a sufferer belongs to two clubs, without the added inducement of compensation for accidental injury. That stock malady, the sprained back, an injury so easily obtained, so successfully simulated, so difficult to disprove, with its entirely subjective symptoms and absence of all objective sign, and so prone to recurrence, with the "railway spines" and "nervous shocks," will be supplemented by other maladies. Ordinary illness, such as a common cold, will be said to be an accident, the result of following one's employment in bad weather, &c.

I am, Sirs, yours faithfully,
G.P.

OPERATIVE TREATMENT IN CERTAIN CASES OF INSANITY.

To the Editors of THE LANCET.

SIRS,—In cases of simple insanity—cases which cannot be referred to any structural lesion of the brain—there can be little doubt that disturbance of the cerebral circulation is an important, if not the essential, pathological factor. Anæmia of the brain and symptoms of mental depression necessarily follow a diminished supply of blood to the organ, and, on the other hand, if it is abnormally increased, hyperæmia and mental excitement will be the consequent effects. In cases in which the quality as well as the quantity of the blood-supply is altered and in which an impediment to the return of blood from the head exists, the effect will not be so simple but will exhibit corresponding complications. Many cases of simple insanity, however, appear to depend almost entirely upon active hyperæmia and increased blood pressure. I allude to cases in which the individual's powers of perception, recollection, thought, emotion, and volition are all more or less intensified as well as perverted. The condition of these patients resembles very closely the delirious state of those suffering from pyrexia which is undoubtedly due to increased blood pressure. To the same cause also may be ascribed the mental excitement produced by stimulants and by the administration of ether or chloroform.

Delirium so closely resembles the acute form of mania that persons suffering from it have been improperly ordered into confinement as maniacs. The diagnostic difficulty is easily explained when we remember that increased blood pressure is the main cause in both cases. Again, in cases of mania the more acute the symptoms the greater the cerebral disturbance and insomnia, the more favourable is the prognosis. In such cases as soon as the flow of blood in the cerebral vessels returns to its normal state the mental derangement disappears, leaving the mind clear, as in delirium due to some febrile disease. There are cases, however, of acute mania which improve up to a certain point and then go no further but remain stationary for an indefinite time and at length exhibit signs of approaching dementia. Now the question arises, How is it that these cases do not recover? Is it because the arteries of the brain have become permanently enlarged and the supply of blood in such cases continues to be abnormally excessive? Can nothing be done to lessen the supply? Why not ligature the carotid artery with this object in view? I have a case under my care of this kind at the present time and should like to hear the opinion of some of your readers on the above suggestion. Would the operation be likely to be of any value? Would it be justifiable to perform it experimentally with the consent of the relatives of the patient?

I am, Sirs, yours faithfully,
August 31st, 1906. M.R.C.S., &c.

THE ELECTRICAL RESISTANCE OF THE BLOOD AND URINE AS A TEST OF THE FUNCTIONAL EFFICIENCY OF THE KIDNEY.

To the Editors of THE LANCET.

SIRS,—My attention has been called to a research by Dr. Dawson F. D. Turner, published in THE LANCET of July 28th, 1906, p. 223, under this title. It is quite impossible to obtain a measure of the concentration of a specimen of blood in salts by measuring the electrical resistance of the blood as Dr. Turner supposes. It has been shown by various observers—first of all by Professor G. N. Stewart[1] and Roath[2] independently of each other—that the coloured corpuscles are practically non-conductors owing to their impermeability to the ions of plasma.

The conductivity of blood depends not only on the salts of plasma but on the relative volume of corpuscles and plasma.[3] The reason why Dr. Turner obtains so marked a diminution of resistance in blood in pernicious anæmia is because the number of corpuscles is so greatly reduced. It is only by measuring the conductivity of the serum that any notion of its richness in salts can be obtained. I have published results of conductivity measurements[4] and freezing point observations on blood and serum in numerous diseases. In pernicious anæmia (three cases) I found no warrant for concluding that the proportion of salt is increased.

I am, Sirs, yours faithfully,
THOS MATHESON WILSON, B.A. Toronto, M.S. Chicago.
Physiology Department, University of Chicago, August 18th, 1906.

WHAT IS A SPECIALIST?

To the Editors of THE LANCET.

SIRS,—As a contribution to the correspondence under the above heading I venture to describe my own case. Four years ago (this coming December) I had to decide whether to resume medical practice as a specialist or as a general practitioner. During the preceding three years I had held a hospital appointment near London which offered me facilities to qualify myself specially in eye, ear, and throat work. The cult of pure specialism seemed to present undue financial risks. I therefore purchased a practice in a town with a population of 120,000 without a resident specialist, and having a children's hospital staffed by general practitioners without a single specialist appointment. I entertained hopes of being able to combine general with special practice. I was prepared to face difficulties, for my five years' experience of general practice had been of educational value in certain directions. On taking up my residence in the town I called upon an unusually large number of my medical brethren and after candidly explaining my position sought their support in my special refraction work, &c. In this connexion, however, I soon discovered that all my *confrères* were bonded by ties of medical fellowship and that they had no "side chains" for a colleague however specialised his claim for professional coöperation. For the first nine months I was content to assist four afternoons a week in the special departments or hospitals of an adjacent city whose medical might overshadowed the town in which I practised. Then I became impatient of playing the part of hospital drudge *pour passer le temps*. The Micawber-like spirit of waiting served me not. The desire possessed me to secure can ascend the Douro to the town of Oporto a port has been artificially constructed some three miles north of the mouth of the Douro by building great sea walls inclosing deep water where large ships can ride at anchor. On the breakwaters there are cranes and other facilities for landing merchandise, while in the north-eastern corner of the shore the new disinfecting and medical station has been built. It consists of extensive brick structures one storey, and in some parts two storeys, high with an embankment and frontage giving on to the water. Here the passengers and their luggage are disembarked and there are spacious waiting-rooms for them, arranged something like those of a railway station.

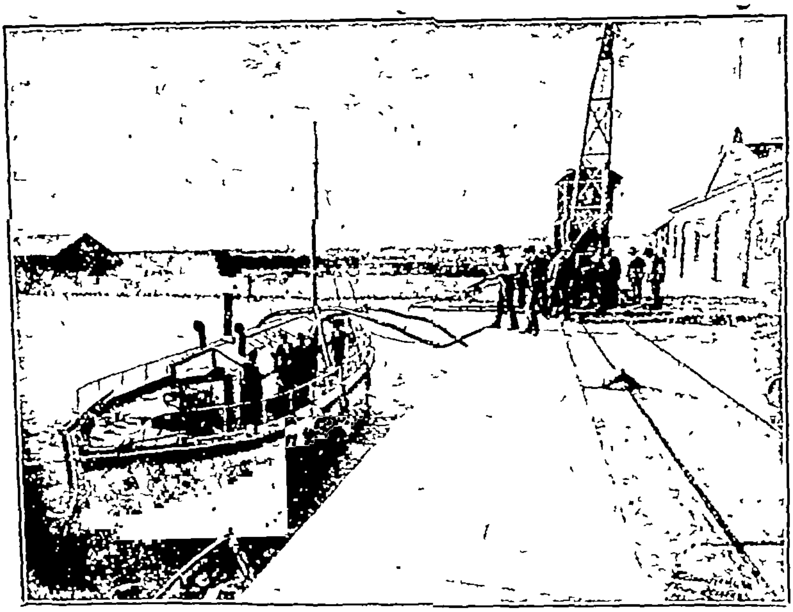
FIG. 1.



The boat containing the Clayton disinfecting apparatus and the pipes through which the fumes can be sent into all the disinfecting chambers of the station on shore or into the hold of a ship anchored in the harbour of Leixoes (Oporto)

Then, close at hand, there are a series of well-appointed baths. These the travellers approach from what might be described as the infected side and undress in a small compartment. While they are bathing in the next, or middle, compartment an attendant fetches all their clothes and places them within the disinfecting stove. By the time the bath is finished the clothes have been taken out of the other end of the stove and conveyed to the third or dressing chamber situated on the non-infected side of the baths. There are also large compartments where luggage and merchandise are disinfected or fumigated by various means. Finally there is a custom-house department where the purified goods are examined with a view to the imposition of custom-house dues Close to this part of the building are railway sidings, so that luggage or merchandise can at once be despatched to its destination.

For disinfecting purposes the Clayton system is very generally used, but instead of being on shore the apparatus is placed on board a boat. Thus it can be brought alongside of the ships that are anchored at some distance from land and there discharges the fumes that kill all the rats and other vermin living between decks. On the other hand, and as shown by the accompanying photographic reproduction, it can be connected with the building on shore. Pipes are jointed together and the fumes from the apparatus are taken to one of the disinfecting rooms. This is especially used for skins and hides that are hung up on the numerous pegs prepared for their reception. Naturally the work of disinfecting the cargo of a ship necessitates the employment of a large number of porters or dock labourers. Therefore it is not only necessary to provide large bare rooms where cargoes can be spread out and fumigated but there are a dormitory and a dining room for the dock labourers where they can dine and sleep while handling goods that may be infected. During that time these labourers are prisoners. They are only let out and allowed to return to their homes when, their work being done, they can bathe and have their clothes disinfected. In the meanwhile they must be provided with meals, and consequently a maritime disinfecting station needs a restaurant establishment on the same premises. Further, there must be means of conveying food from the kitchen to the infected portion of the station without personal contact. This is done by an aperture in the wall. The food is placed on a circular tray divided vertically by a partition which closes the opening in the wall. A pivot enables the loaded half of the tray to be sent round to the other side of the wall. In the same manner the plates are returned to the kitchen. This method is also employed for passing in the food and other things to the small isolation hospital with which the disinfecting station is likewise provided. Thus, a few patients could be removed from a ship and nursed at the disinfecting station. There is, however, no accommodation for placing in quarantine a number of passengers or sailors. If this was necessary the ship would have to proceed to Lisbon.

(To be continued.)

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

Coöperators and a Liquor Licence.

SOME time ago an hotel at Gillsland was taken over by coöperators of the northern section of the Coöperative Union and converted into a convalescent home. The question then arose as to what must be done with the licence. Some considered it inconsistent for them to have anything to do with the liquor traffic. Others thought that if they gave up the licence someone in the neighbourhood would apply for it, and the facilities for drinking would remain the same, while the directors of the home would lose all control over the sale of intoxicants. The licence was retained. The question came up again at a meeting held on August 24th, when there was an animated discussion on the matter. A resolution from the Hartlepools Society dealt with it as a question of expediency, that it was hurtful to the best interests of the home, that a number of societies would not become shareholders on this account, and proposed that the directors be empowered to allow the licence to lapse at the next session. Many of the speakers said they up some branch of the profession which is uncongenial and so to "make a mess" of their lives.

Having, however, passed the examination for the Fellowship, and having so become qualified to follow his profession as a pure surgeon by reason of the appointments thrown open to him, the "fortunate" young man has to spend several years in which he might be improving the science and art he has adopted, and his own mind in particular, in grinding out the elements of anatomy to men who will never want one-twentieth part of what is taught them, or in writing a book before he has had the necessary experience of the subject. When he is past his prime he will perhaps get the chance of practising surgery. At a later stage, just when a record of his experience would be of infinite value to the profession, he is far too sick of it all to set it forth, and little wonder; moreover, he has no incentive in the form of future gain. I maintain that this state of things is not conducive to the advancement of the science and art of either surgery or medicine and it follows that the ranks of the specialist, who, either by natural selection or again by chance, are at present taken from a small class, are not filled so well as they could be were the process of selection different. This is undoubtedly to the great loss of the nation.

I am, Sirs, yours faithfully,

August 26th, 1906. UNLUCKY PLODDER.

PORTUGUESE QUARANTINE REGULATIONS.

(FROM OUR SPECIAL SANITARY COMMISSIONER.)

PART I.

THE NEW LAW ON MARITIME SANITARY PRECAUTIONS.—THE NEW MARITIME DISINFECTING STATION AT OPORTO.

IN respect to maritime sanitation Portugal has a policy of its own. It is governed by a law dated Dec. 24th, 1901, which may be considered an improvement on the international convention adopted at Venice in 1897, though in several respects it is inferior to the international convention subsequently approved at Paris in 1903. In any case, the main practical fact is that communications with Portugal by sea are now less liable to be impeded by sanitary or quarantine regulations. Undoubtedly Portugal had good reason to be on its guard. It is a poor country and large sections of its population overcrowd very old and insanitary dwellings where they may lack sufficient or suitable food. But apart from these general predisposing conditions, there is a specific reason why the country should have frequently suffered from the importation of epidemic disease. A very large proportion of the maritime trade is with the Brazils and South America where yellow fever abounds among other pestilences, and Portugal has good reason to be careful especially in regard to yellow fever. The bilge water in the old wooden ships facilitated the importation of the larvæ of the stegomyia, and the conditions of the modern copper-bottomed ships are not so favourable to the development of mosquitoes, but, nevertheless, the precautions now taken are less irksome than formerly while losing nothing in thoroughness.

A few years ago when a ship arrived at Leixoes, which is the port for Oporto, it had to proceed to Lisbon if refused free *pratique*. This is a journey for a steamship of from 12 to 15 hours and involves a great loss of time, coal, and general working expenses. Lisbon was the only port in Portugal possessing a suitable disinfecting station for cases of yellow fever, plague, or cholera. When the cholera prevailed at Hamburg and at Havre ships could not land their passengers or goods at Oporto, for it took less than seven days to come from the infected German and French ports. So great was the trouble and the loss that the Oporto Commercial Association determined to erect a disinfecting station at its own expense and thus save the loss incurred in sending ships and passengers to Lisbon. The new law of 1901 rendered the expediency of such a measure more obvious. According to this law a Portuguese port can only be declared contaminated by the Minister of the Interior through the Director of the Department of Public Health and after the opinion of the General Inspection Services and of the Superior Council of Hygiene has been obtained. Even then the presence of cases of plague, cholera, or yellow fever can only be declared when their origin is such as to occasion peril from a sanitary point of view. Undoubtedly a considerable time must elapse between the notification of the first case and the accomplishment of the above stipulations. In the interval considerable mischief might be accomplished; nevertheless the law formally states that the Government alone has the right to proclaim the presence of epidemic disease in a port, and that the port sanitary authority shall not issue a *patente brute* till after such Government declaration has been officially made. It is known that there are three sorts of *patentes*. The *patente nette* is given when the sanitary and health conditions are all that is desirable. The *patente brute* makes no specification, and *patente suspecte* does not affirm that the state of health on board was good at the moment of departure. Thus it is evident that the Portuguese Government is very anxious that no unnecessary and premature alarm should be raised; yet it is equally evident that if there be any virtue at all in these sort of precautions this must depend on their being enforced in time.

In regard to the precautions which the new law stipulates must be taken against ships arriving in Portugal, these differ according to the supposed degree of danger, and many clauses in the Act are necessary to deal fully with these varying conditions. Thus there are ships coming from a healthy port with all well on board, but which have had some suspicious communication while in the open sea, or which have an unfavourable anterior record, or have no surgeon on board, &c. Then there are ships that have stopped for a short time in an unhealthy port. But, and so as not to enter into minute details, the main principle is that the ship must have been at sea seven days without there being any infectious case of sickness on board. If a ship arrives with all well on board but with a *patente brute* as coming from a place known to be contaminated, and has been more than seven days at sea, *libre pratique* is granted to all the passengers after they have undergone a rigorous examination. Their dirty linen, however, is disinfected. The ship and its cargo will be isolated and disinfected and the crew will be disinfected and subject to further medical examinations during seven days. If a ship under the same conditions has been less than seven days at sea the passengers are allowed to land, but they must undergo a rigorous personal disinfection and are only allowed to proceed to places where they can and will be watched medically till the seven days are completed. Should there, however, have been cases of illness on board, and even if these cases terminated by death or recovery more than seven days before the arrival of the ship, the passengers may be detained in quarantine but not for more than 48 hours, and then, when set free, they are to be watched when they reach their destination for seven days more. But this comparative leniency only applies to ships that are in a good sanitary condition and carry a surgeon and a disinfecting stove on board. If these conditions do not obtain then the ship is treated as if there had been cases of illness during the seven days previous to arrival. In that case the passengers are disembarked and isolated in a lazaret where they are kept in rigorous quarantine for seven days. Their luggage and persons are, of course, disinfected, as are also the ship and its cargo. The crew is treated in the same manner. When the danger is that of plague and if the ship has been to a plague-stricken port within the previous three months, or has on board goods coming from a plague-infected locality, all the rats on board must be destroyed and some of them sent to the bacteriological laboratory for examination. If the analyses show the presence of plague among the rats then the entire ship and its cargo must be rigorously disinfected. The same measures must be adopted if the rats die spontaneously on board in such a manner as to make it appear that they are suffering from plague.

Such being some of the more important regulations it will easily be understood that large maritime stations desire to have within easy reach all that is necessary to carry out the law. As, however, the Government is slow to provide the means of applying its own law, the merchants of Oporto spent out of their own pockets some £33,000 to build a disinfecting station at Leixoes and thus avoid having to send ships to Lisbon. Dr. Oliveira is at the head of this institution, and when I was passing recently through Oporto, he very courteously invited me to visit it. As only small ships houses have been built and 175 new streets have been laid out. Water carriage of excreta is almost universally adopted and a well-equipped isolation hospital receives 80 per cent. of the cases of infectious disease occurring in the borough. It might be expected therefore that Newport would have a much better record as regards infantile mortality than some of the large northern towns which are not so well circumstanced either as to housing accommodation or with respect to other sanitary conditions. During the ten years 1895–1904 the infantile mortality rate averaged 159 per 1000 births and in 1899 it was as high as 188 per 1000 births. In 1905 it was 126 per 1000. This decrease in the mortality among young children is due in part to the improved water-supply and in part to the employment of a female health visitor. For several years prior to 1904 there was a distinct shortage of water in the summer months. As the corporation makes an extra charge for water supplied through a cistern to water-closets many of these are hand-flushed and in times of scarcity are very inefficiently flushed, so that some of the worst features of a privy closet would be produced. The health visitor was appointed in 1892 and is evidently doing good work. During 1905 she paid nearly 1500 visits to houses from which births had been registered and gave advice on infant hygiene and wherever infantile diarrhœa was known to exist she gave information as to the proper dieting of children. The results indicated above are quite sufficient justification for the appointment of this officer. Voluntary notification of phthisis has not been very successful in Newport. There were 68 deaths from this disease during 1905 and only 21 cases were notified. Now that the corporation has decided to utilise one of the blocks at the isolation hospital for the treatment of consumptive patients the number of notifications will probably be increased.

Hereford Dispensary.

This institution has been established over 70 years and includes a provident as well as a charitable branch. During the year ending at midsummer last there were 412 provident members who subscribed £221. Of this sum £155 were distributed among the medical staff and the remainder was placed to the charity account.

The Handel Cossham Hospital, Kingswood.

The Handel Cossham Hospital, which is being erected at Kingswood, near Bristol, at a cost of £27,000, exclusive of furnishing, is now approaching completion and it is expected that the formal opening will take place early next year. The hospital has an endowment fund of £80,000. The total cost of the undertaking was provided for by the late Mr. Handel Cossham, a former Member of Parliament for Bristol.

The Truro Board of Guardians and its District Medical Officer.

At a meeting of the Truro (Cornwall) board of guardians held on August 30th Dr. James Ratcliff-Gaylard attended and complained of some remarks made at a previous meeting of the guardians, when it was stated that the medical officer had been in the habit of sending to the asylum with undue haste persons who were not insane and ought not to be sent there. In protesting against these remarks he said that it was open to him to bring an action for libel against the board and he produced a letter from the medical superintendent of the asylum stating that persons who were not insane would not be kept there. After some discussion the guardians unanimously passed a vote of confidence in Dr. Ratcliff-Gaylard who in acknowledging it expressed himself as being entirely satisfied.

The Devon County Council and Tinned Meat.

At a meeting of the Devon standing joint committee held on August 29th it was reported that during the preceding three months 40 samples of tinned meat had been submitted for analysis under the Sale of Food and Drugs Act and that "grave fault had been found with some foreign brands, the county analyst having in some cases certified that the contents of the tins were unfit for human consumption." It was suggested that the committee should issue some warning notice but the chairman expressed the opinion that nothing would be more effective than the revelations published in the newspapers, adding that the defects were entirely in foreign manufactured products.

Sept. 4th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

The Water-supply in Islay.

THE question of water-supply for the villages of Portnahaven and Port Wemyss in Islay has been for some time engaging the attention of the local authorities. In the month of July Dr. Robert McNeill, the medical officer, and Mr. Campbell, the sanitary inspector of the county of Argyll, submitted a report to the district committee in which they stated that the water in the reservoir for supplying the villages was found to contain more nitrogenous and suspended matter than is desirable in water used for dietetic purposes, that the reservoir was in several places at the sides overgrown with weeds, and that its bottom appeared to be covered with mud. The provision for filtration was so inefficient that the people complained that tadpoles issued from the pipes, some stating that a teacupful of tadpoles could be found sometimes in a pitcherful of water. With the exception of one man the villagers informed the inspector that they never use the water-supply provided by the district committee for dietetic purposes but drew their water from surface wells. In these wells for the most part the supply of water was pure but the quantity was limited, and one well was found almost dry and swarming with water-flies. In connexion with the water-supply from the reservoir there is no grave source of pollution, and it is thought that by proper filtration, cleansing of the reservoir, removal of weeds and mud, protection of the stream from cattle, and also by the frequent scouring of the pipes the water might be rendered fit for household purposes. The matter has been brought under the notice of the Local Government Board and recently the district was visited by Dr. F. Dittmar and Mr. Carter, C.E., and Dr. McNeill, the sanitary adviser of the Local Government Board.

The Dangers of Shell-fish.

Last year, as was noted in THE LANCET, there was a mild epidemic of enteric fever in the summer months traceable to shell-fish gathered and eaten by trippers to the various seaside resorts on the Firth of Clyde and east coast of Scotland. In consequence of this it was suggested by the medical officer of health of Glasgow that the authorities at the various watering places should erect boards bearing notices warning people from gathering mussels in areas where it was considered they could not be obtained uncontaminated by sewage. Notwithstanding this precaution six cases of enteric fever have just been reported in Glasgow apparently arising from this same cause. In three cases the shell-fish were gathered on the west and the remainder on the east coast. In one instance on the west coast no notices warning the public regarding the danger arising therefrom were to be seen, although in another they were read and disregarded. It would appear also that the east coast local authorities have not yet adopted this measure of warning the public, although in one instance it is reported that the situation from which these shell-fish were gathered was grossly contaminated with sewage. It is now suggested that the local authorities should adopt preventive measures by framing by-laws prohibiting the public, under penalty, from gathering shell-fish in other than the descriptive areas laid down by them—i.e., such places remote at least a quarter of a mile from sewers or other contamination, with all due regard to the ebb-flow, eddies, &c.

Retirement of the Surgeon to the Glasgow Police Force.

Dr. John A. Boyd, who for some years has held the post of medical officer to the Glasgow police force, the fire brigade, and lighting department, has tendered his resignation owing to continued ill health and the resignation has been accepted. It has been stated that the medical man who holds this post has to attend in case of illness about 3050 men, and it is suggested that it would be advisable instead of appointing one medical man to appoint several and divide the work into districts, as was done recently in the case of the Post-office appointment in Glasgow. This suggestion has not met with the approval of the watching and lighting committee of the town council in the hands of which the appointment lies. The committee has agreed that applications for the post should be advertised for at a salary of £400 per annum, with an allowance of £10 per annum for bandages, &c. and £50 per annum for travelling expenses.

Sept. 4th.

were teetotalers and some were interested in temperance reform, but they thought the licence safer in their hands than in those of a private brewer, as they do not push the sale of drink either among visitors at the home or the people of Gilsland. The voting showed 44 in favour of letting the licence lapse and 149 in favour of its retention. This apparent anxiety lest a dangerous power should fall into hands less scrupulous than those of the coöperators seems to be discounted by the statement that there was no real need for the retention of the licence, as those who wanted intoxicants could get them from other licensed houses in the neighbourhood. The conclusion come to makes things easy for those who love compromise, for the coöperators keep control of what is so often a curse and at the same time obtain their special beverages with the least possible inconvenience. So far as the legitimate work of the home is concerned the report appears satisfactory. There were 596 convalescents in the home during the year, the same number as in 1905, while 787 visitors had made use of the home, as against 670 in the previous year. During the month of June all the accommodation was occupied; since Easter it has been well utilised. These convalescent homes in different parts of the country are among the brighter signs of the times. They show that the principle of self-help is extending in some directions.

The Fascination of the Brickcrofts.

To ordinary people the prospect of sleeping in a brickcroft, even with the warmth of the kiln as an additional temptation, is not one that would be looked forward to with pleasure. To some men, however, it does seem to present a fascination not altogether accounted for by necessity. The representative of the firm owning the favourite brickfield at Cheetham told the magistrate's clerk that they could not keep the men away. When turned off they came back in "a larger batch," though they had a yardman and a watchdog. The men carried the hurdles and boards into the drying sheds and created a nuisance there. One man said he was homeless, out of work, short of food, and out of health, but a large proportion might have better quarters if they thought it worth their while to make a little effort. The Bench ordered food to be given to the homeless one and sent him to the Crumpsall workhouse. Some were discharged, but others were sent to prison for periods ranging from seven days to a month. The struggle to prevent the use of the brickfields as a sleeping-place has been going on for a long time and it seems as far from a conclusion as ever. This is not the place to go into the question of the "submerged," but their existence shows a failure in our social system not creditable to the civilisation of to-day. The point of most interest to us as medical men is the part played by them in the spread of disease.

Death of Mr. A. G. Don of Stockport.

The death by motor accident of Mr. Don, who removed from Sevenoaks to Stockport about three years since, adds one more to the roll of those slaughtered by motor-cars. This slaughter has become so frequent as to be commonplace and the docile British public looks on it as belonging to the established order of things. An inquest was held at Sevenoaks, where Mr. Don was staying for a short time, on August 25th. The verdict, of course, was "Accidental death," the driver being exonerated from all blame. But the jury added a rider to the effect that only competent men should be licensed to drive motors on the public highway, the jury considering that the driver had not had sufficient experience. This does not agree logically with the verdict, but it shows what all must see, that with the immense and rapid multiplication in the number of motor-cars there must have been a corresponding increase in the number of drivers, and therefore the more probability of a large proportion of them being incompetent. The cause of the overturning of the car was from sideslip on a muddy road.

Sept. 4th.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

Liverpool Health Committee: the Public Milk-supply.

AT a meeting of the health committee held on August 30th Dr. E. W. Hope (the medical officer of health) reported that the number of deaths during the preceding week was 345, equal to a rate of 24·2 per 1000, as against 19·9 a year ago. He said that the death-rate was a favourable one considering the meteorological conditions, &c., but the continuance of the present hot weather would probably give rise to a further mortality from diarrhœa in infants, unless great care was bestowed upon them by mothers, especially in the matter of feeding. The general hospitals were available to admit such cases, being temporarily subsidised by the corporation; suitable food was also supplied by the same body; but unless mothers themselves were particularly careful in regard to the management of their infants there would certainly be a continuance of the mortality from diarrhœa, which last week accounted for 127 deaths, as against 77 in the corresponding period of last year. Two fresh cases of small-pox were reported during the week, making five now under treatment in hospital. Having regard to the importance of the public milk-supply the health committee has authorised Dr. Hope to attend a conference of medical authorities shortly to be held in London on the question. The conference will be arranged for at a date generally convenient and will probably take place a month hence.

Enteric Fever at Fleetwood Camp.

An outbreak of enteric fever has recently occurred among the officers of the 3rd Battalion of the Loyal North Lancashire Regiment quartered at Fleetwood Camp, nine of whom were attacked by the disease and three unfortunately have died. Special inquiries are being made as to the cause of the outbreak. The *Liverpool Daily Post and Mercury* states that the governing body of the town has no jurisdiction over the camp which is on Crown land. The authorities have assisted Major Pearse, the War Department's specialist, in his investigations. Two facts are established—firstly, that the outbreak is limited to the officers' mess and, secondly, that the cause must be either the food or the water. All the food recently purchased in the town and neighbourhood has been traced as far as possible, but everything is reported as being absolutely above suspicion. The water-supply to the camp is exactly the same as that supplied to the town as well as to Blackpool, Lytham, and St. Anne's, and all the neighbouring places. No sickness exists in the camp and Fleetwood's bill of health is quite clean. The water supplied to the officers came from pipes laid by the War Office, the joints of which were found to be bad and leaky, and it was stored in a certain water-barrel cart which seems to have been in a dirty condition. The water has evidently been contaminated from one or both of these sources.

Lunacy in Lancashire: Asylums Board Scheme.

The Local Government Board has consented to the Lancashire Asylums Board borrowing £29,000 for the purchase of the Whalley estate as a site for a new lunatic asylum. The site committee deemed it wise to refrain from erecting a complete asylum for 2000 patients, but decided to erect a portion, leaving time and opportunity of gaining greater experience before deciding upon a plan for the remainder. Of the 13,000 or 14,000 certified pauper lunatics in Lancashire one-fourth are maintained in the workhouse at a substantially less cost to the ratepayer than in the asylum. A conference with boards of guardians is discussing the possibility of arriving at an arrangement whereby a large proportion of chronic and harmless cases shall be maintained at the cost of the asylums board in workhouses, while acute and dangerous cases in the workhouses could be sent to the asylums. The erection of a reception hospital and administrative block with wards attached for 500 acute curable cases of each sex has been recommended.

Sept. 4th.

WALES AND WESTERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENTS.)

The Public Health of Newport.

THE most satisfactory feature in Dr. Howard Jones's recently issued report on the health of Newport (Mon.) is the decline in the infantile mortality rate during 1905. A very large portion of the town consists of newly-built houses which have presumably been erected in compliance with modern requirements. During the past 18 years over 7000 and Medicine of Montpellier. An annual prize in legal medicine at the Faculty of Medicine is provided for, and a similar prize is provided for in the Faculty of Law. A life annuity of 10,000 francs is left to an aged relative which reverts at her death to the Faculty of Medicine.

Dysentery at Toulon.

An epidemic of dysentery is reported from Toulon in the 111th Infantry Regiment stationed in a barrack a portion of the buildings of which is of great age. Many soldiers have been sent to the infirmary and many others to the naval hospital. Careful sanitary precautions have been taken. The water-supply has been brought in from outside and if necessary the barrack will be evacuated.

Action of X Rays on the Ovary of the Bitch.

M. Bouchard read a paper upon this subject at a meeting of the Academy of Medicine held on August 6th. The experiments in question were made by M. Roulier. Last year three observers showed that x rays in weak doses could bring about atrophy of the ovary in rabbits. M. Roulier repeated these experiments upon both rabbits and bitches and found that x rays had a selective action on the ovaries. In very small animals atrophy could be easily brought about without the production of any loss of hair. In the bitch, however, it is very difficult to obtain, even though the administration of x rays was carried to the extent of bringing about lesions of the skin. It would appear impossible to bring about atrophy of the ovary in woman, since experiments upon the corpse of a woman showed that x rays No. 10 were unable to modify the colour of a radiometric pastille placed over the ovary.

The Condition of the Blood in Insanity.

At the Sixteenth Congress of Medical Alienists and Neurologists held at Lille on August 1st M. M. Dide opened a discussion on the Condition of the Blood in Insanity. He first dealt with its behaviour on issuing from a wound, its colour, its alkalinity, and the determination of the mineral constituents. He said that in epileptics the specific gravity of the blood showed a diminution immediately before the occurrence of a fit but very soon regained its normal degree. The proportion of red corpuscles was above the average in maniacal conditions and in the mild forms of general paralysis. In dementia præcox during the early stages of mental depression there was sometimes well-marked leucocytosis with polynucleosis and sometimes eosinophilia. Leucocytosis was hardly ever found in general paralysis apart from febrile and convulsive attacks, in which short periods of leucocytosis were the rule. In epilepsy there was a leucocytosis of brief duration which probably began immediately after a fit. In melancholia with occasional excitement the periods of excitement were characterised by a slight leucocytosis with a normal or very slightly diminished proportion of polynuclear cells during the periods of depression. The microbes found in the blood of insane persons were the enterococcus, the staphylococcus, the micrococcus tetragenes, and on rare occasions the streptococcus. Although organisms could often be cultivated from the blood none of them could be regarded as specific. In his remarks on the chemical physics of the blood M. Dide touched on the methods of procuring samples, on the colouration of the serum, on the occurrence of bile in the serum, on cholæmia affecting members of a family, on laking or the staining of the serum with hæmoglobin, on opalescence of the serum, on glykæmia, and on increased osmotic tension (*hypertonic*) of the serum. He then proceeded to the consideration of alexins, bacteriolysins cytolysins, specific and non specific neurolysins, isohæmolysins antihæmolysins anticytotoxins, specific and non-specific natural antihæmolysins, bacterial hæmolysins, agglutinins, precipitins, hæmo-agglutinins, bacterio-agglutinins, antibacterio-agglutinins, toxins of parasitic origin, chronic and acute microbial toxins, and meta-infectious neuro-toxin. In conclusion, he discussed hæmatology in relation to heredity and the effects of lesions of organs or structures which were concerned in the defence of the body against toxic agencies, such organs or structures being exemplified by the bone marrow, the lymphatic glands, the liver, and the glands of internal secretion. Among the subsequent speakers who took part in the discussion were M. Sabrazès, M. Taty, M. Sicard Léri, and M. Faure.

Sept. 3rd.

ITALY.

(FROM OUR OWN CORRESPONDENT.)

Alexander Herzen.

THE week now closing has been saddened for many Italians by the death of Alexander Herzen at Lausanne, where he had long been enhancing in the chair of physiology the reputation he founded in the same capacity at Florence. Son of the celebrated Russian patriot and man of letters, he was born on June 29th, 1839, and sharing his father's "disabilities" in his native country he made Switzerland the scene of his studies, first literary, then medical, in which latter he distinguished himself at Berne, where he graduated as M.D. in 1862. After a visit, for scientific purposes, to Ireland, he came in 1865 to Florence as assistant to Professor Moriz Schiff, then occupying with great distinction the chair of physiology in the "Istituto di Studi Superiori." He worked assiduously and effectively with his master in those researches in the nervous system and in digestion which at that time gave Florence a European name, and when, on the occasion of Professor Schiff's jubilee, a selection from his works was made *publici juris* in various languages, Herzen was intrusted with the edition in French of his master's great treatise on the "Digestive Process" For 12 years he continued his conjoint labours with the Florentine professor till, under pressure of antivivisectionist agitation, in which the English-speaking colony took an active and far from creditable part. Schiff had to transfer his brilliant and salutary services to Geneva. Herzen then succeeded him in the "Istituto," but in four years had to follow his master to Switzerland, there to act as professor of physiology at Lausanne. From 1881 to the present year he made his chair progressively attractive to students of every nationality, while he will always be gratefully remembered in the canton and in the country as one of the most effective organisers of the new University instituted in 1890. Switzerland had by this time become his native country, in which he represented loyally the views, political and social, which had driven his father into exile—in proof of which may be cited his refusal to accept the restitution of his confiscated estate and fortune offered him by Alexander III. on condition of his renouncing his father's opinions. He was a voluminous but at the same time a weighty and estimable contributor to the literature of his subject, some of his best work having seen the light in Italian, a language in which he wrote and conversed with an idiomatic ease and elegance equally conspicuous in his French and in his German. Of his ten children some were born in Italy, one of them at present holding office under the Italian Government in the Department of Woods and Forests. His death at Lausanne, due to an apoplectic seizure from which he never rallied, became known in Italy on August 28th and evoked poignant regrets in many a circle, scientific, professional, and lay.

National Congress for the Blind.

The annual "Congress" has long been to the profession in Italy what the "post-graduate course" has been in Northern Europe and has quite lately come to be in Italy herself. It was, and is, an opportunity widely and effectively utilised of a professional "comparing of notes" and interchanging of experiences, mostly clinical, which is now systematically afforded in supplement to the medical curriculum at the various schools. The next two months will witness many of these congresses, embracing discussions on the most diverse topics of medical interest, from clinical diagnosis and therapeutics to hydrology and balneary appliances, from public hygiene to the care and (where possible) the cure of the blind. This latter theme will attract to Rome in the late autumn a large assemblage of all interested in the conservation of the visual organs and in the means of aiding those whose eyesight has failed them congenitally or by accident or disease. King Victor Emanuel is expected to honour with his presence this (the Fifth) "Congresso Nazionale per la Prevenzione di Cecità" and the Minister of Public Instruction, who will also preside, has already contributed 1000 fr (£40) towards general expenses. Two committees, one organising and another honorary, are coöperating for the successful issue of the Congress, at which many important papers will be read and discussed by masters, past and present, in the two main sections, that of "Typhlology" and that of the "Prevention of Blindness." While the Congress is sitting

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Longford County Infirmary and its Medical Officer.

AT a recent meeting of the committee of management of the Longford county infirmary a long and elaborate report was read from the Local Government Board with reference to certain charges made by the committee against Mr. N. Mayne who has been surgeon to the infirmary for 30 years. Dr. Hoare, Roman Catholic Bishop of Ardath, presided. The report dealt fully with the subjects of the inquiry held in March last, when the surgeon was charged with disobedience and insubordination, and went also into the charge brought against him on June 26th of having caused an outbreak of diphtheria in the hospital by his admission of a patient suffering from that disease. The report states that apart from the question of the outbreaks of diphtheria the general charges preferred against Mr. Mayne had reference to differences of opinion between him and the committee of management. As regards the admission of a patient without a ticket the matter was exhaustively discussed at the inquiry, and the board considered that when the patient was brought to the infirmary the surgeon could not have done otherwise than admit her, having regard to the urgency of the case and the necessity for immediate operation. As regards the selection of consultants the board considers that the committee having fixed the rate of remuneration would act prudently in leaving the selection of a consultant to the surgeon who is in the best position to judge what special assistance he requires at each operation. Regarding the recent outbreaks of diphtheria in the institution the board referred to the evidence of Dr. J. M. Day, resident medical officer at Cork-street Hospital, in which he stated that if towels were properly disinfected there would be no danger of contagion being conveyed by them. Moreover, if the infection had been conveyed by them symptoms would have appeared before March 27th. The towels had been used by Mr. Mayne in a private case of diphtheria and belonged to the infirmary. The board, however, considered that the practice of the surgeon in taking the infirmary nurse to assist him in his private practice was irregular, and it was also highly irregular that towels or other surgical requisites belonging to the infirmary should be used by Mr. Mayne outside the infirmary, while it was particularly objectionable to have used them in such a disease as diphtheria. But the report on the whole is distinctly in favour of the well-known surgeon to the Longford Infirmary, for it states that it is of opinion that "while there have been irregularities no grave dereliction of duty has been proved."

Typhoid Fever in Belfast.

At a meeting of the city corporation of Belfast held on Sept. 3rd an influential deputation, representing residents in the Malone road district, appeared before the council with reference to an outbreak of typhoid fever in this locality. It was stated by the two spokesmen that 14 cases had been already reported, and that there were others not yet reported, and that relatives of some of the deputation were suffering from the disease. The corporation was urged to take measures for real adequate protection of the milk-supply, especially outside the city. No milk, it was suggested, should be sent from a dairy which had not a proper licence from the corporation. There should be adequate inspection both of the cows and of the people who milked them. The sewerage of the district was also referred to and the presence of open gratings was condemned. The council was urged to take some energetic action in such a very serious matter. In the subsequent discussion (on the report of the public health committee) it was admitted that the health authorities were not able to fix the blame on any particular cause, though there was, it was stated by the chairman of the public health committee, suspicion attaching in some direction. It was pointed out by another speaker that it was deplorable that, in the face of such an epidemic in one of the most prosperous districts of Belfast, there should be no one at the head of the public health department who could be looked to for advice in the matter. The chairman of the public health committee, in reference to the want of proper control of the milk-supply, said the corporation was exercising what powers it had, and he regretted that the Bill which was introduced last session as an amendment to the Public Health Bill had been withdrawn. But why has not the Belfast corporation, in the many Bills which it has introduced, not already grappled with this milk problem? The chairman of the public health committee, in reply to a question at the council meeting, said "he understood that 11 houses where typhoid fever had broken out obtained their milk from the same source." The corporation has been urged again and again to take action as other cities have done, but nothing happens. And the city of Belfast for the past four months has had no medical officer of health. The public health committee, urged on to do its duty by the Local Government Board, has decided by a majority to recommend a salary of £800 a year and a special meeting of the council will consider the whole subject on Sept. 5th.

Tuberculosis in Pork.

For two hours on Sept. 3rd the members of the Belfast corporation discussed the regulations for inspection of pork. The rule formerly in use was to follow the dictum of the 1898 Royal Commission on Tuberculosis and destroy the whole carcass of a pig which on inspection showed any evidence of tuberculosis. To this the Belfast Provision Curers' Association objected on the ground that further experience showed such a rigid rule was not necessary, that it was absurd to treat the pig differently from the cow, and that it was contrary to the practice of Germany and America and to the line adopted in such places as Glasgow, Aberdeen, Birmingham, &c. After a long debate the following resolution was passed by 30 votes to 17:—

> That in all well-nourished carcasses of pigs where the tuberculosis is strictly confined to the glands of the neck, the head only, or such portion as is affected by the disease, shall be destroyed, the remainder of the carcass being handed back to the owner; and that all carcasses showing unmistakable evidence of the disease having become generalised—i.e., two or more organs affected—the whole of every such carcass shall be destroyed, and that all other carcasses showing unmistakable evidence of the disease shall be destroyed.

Previous to the discussion a deputation from the Trades and Labour Council appeared before the council asking them not to modify the old regulations. It is interesting to watch the zeal of some members of the Belfast corporation to abolish tuberculosis by meat inspection while so little is done in other directions, such as sanitation, control of the milk-supply, building of sanatoriums, &c., to face the problem.

Sept. 4th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Toxic Phenomena following the Administration, per os, of Dead Glanders Bacilli.

AT the last meeting of the Society of Biology held on July 28th M. Catacuzene and M. Riegler communicated a paper upon the above subject. They had observed that the intra-stomachal injection of dead glanders bacilli gave rise to grave symptoms in guinea-pigs, whether young or full grown. The symptoms were those of poisoning followed by death at longer or shorter intervals, or by recovery according to the dose of microbes employed. The preparation of bacilli employed was a culture on glycerine agar, emulsionised in alcohol, in which the bacilli died in a few hours. This emulsion was then centrifuged and the dead bacilli were dried in vacuo. When injected into the intestine the dead bacilli gave rise to toxic symptoms varying in gravity with the size of the dose. Not only the soluble portions of the substance but the very bodies of the bacilli themselves passed out through the intestinal walls and could be detected in the lymphatic glands, in the spleen, and in the lungs, in which last organ they produced foci of broncho-pneumonia. Small doses given by the mouth produced a tolerance for the poison provided that three months were allowed to elapse between two doses.

A Medical Man's Will.

Dr. Jaumes, a professor of the Medical Faculty of Bordeaux, has recently died and has made the Faculty of Medicine his legatee. A sum sufficient to produce an annual income of 6000 francs is left for the creation of a chair of general pathology and therapeutics. A sum of 30,000 francs is left to the Association of Medical Men of Hérault and a like sum to the Academy of Sciences, Letters, healthy place until malaria was introduced there in 1877, apparently by Italian workmen engaged on the fresh water canal. Ever since the beginning of the British occupation the town has had a bad reputation for malaria, and before anything was known of the etiology of mosquitoes the fever was thought to be caused in some mysterious way by the meeting of sea water from the Mediterranean, from the Red Sea, and from the fresh Nile water brought by an open canal from Cairo to supply the inhabitants. In 1901 Prince d'Arenberg, the president of the Canal Company, determined to try to stamp out the disease and practically succeeded after two years' exertions. The company is practically master of the situation at Ismailia, and as most of the European inhabitants are in the company's service it was easy to see that medical advice was followed, while full pay and free medicines were granted to the sick. In July, 1901, no anopheles could be found in either the European or native quarter, but at the beginning of August the first were seen, and a few days later the whole town was invaded, the chief varieties being anopheles pharoensis and anopheles chaudoyei. Dr. Pressat was sent to Italy to complete his knowledge of the connexion between malaria and mosquitoes, but it was not until the visit of Major Ross in September, 1902, that the Canal Company, in coöperation with the Egyptian Government, decided to destroy, not only the anopheles, but also the culex and stegomia mosquitoes. Three favourite haunts of anopheles, consisting of small and large swamps, were discovered and had to be drained and filled up at a cost of about £2000. One European and three natives were detailed for applying petroleum once a week to cesspools and to see that water was not allowed to lie in or near the houses. On this day the garden fountains and watering-tanks are obliged to be emptied, and measures are taken to see that all ventilators from cesspools are capped with wire netting to prevent the escape of mosquitoes from the petroleum in the cesspools. The annual cost comes to about £750 As a result of the work mosquito nets have not been necessary in Ismailia since the beginning of 1903, and since that year no case of recent malaria has been known in the town. When any cases of malaria have occurred lately they have invariably been due to relapses in old patients, or the disease has been imported into the town from native villages outside the protected zone. It is now to be hoped that these outlying villages will also be treated by the Egyptian Government, and that the Canal Company will continue its useful labours in Port Said and Suez, in both of which towns there are many mosquitoes and at times much malaria. The statistics for Ismailia show that in the year 1901 there were 1990 cases of malaria treated, whereas in the year 1905 there were only 55 cases under treatment, and everyone of those was a relapse occurring in a chronic patient.

August 28th.

NEW YORK.

(From our own Correspondent.)

Progress of Medicine in the Philippine Islands.

Dr. Victor G. Heiser, surgeon of the United States Marine Hospital Service and Director of Health at Manila, in the Philippine Islands, reports that the past year has been one of great importance in its relation to medical progress in the islands. The most notable event was the passage of an Act by the Philippine Commission establishing a medical school and defining the manner in which it shall be controlled and conducted. It was to be located in Manila and be known as the "Philippine Medical School." The managers are the Secretary of Public Instruction, the Secretary of the Interior, one member of the Commission, and a member designated by the Governor-General. The object of the Commission was to create a class of native physicians, as it is believed that if there was one such qualified practitioner to every 1000 inhabitants the most beneficial results would follow. During the year Saint Paul's Hospital, in Manila, has been established; the Episcopal Church has made the necessary arrangements for establishing a general hospital; the Methodists have opened a dispensary and will soon establish a maternity hospital; the navy has completed a fine modern hospital at Canacao; the army has completed a modern hospital at Fort William McKinley; the Presbyterians have built a large general hospital in Iloilo; and the Government maintains a sanatorium in the mountains of Benguet. In addition to these institutions dispensaries have been established in a large number of places by church organisations or by the Bureau of Health. The report calls attention to researches which Dr. Wilkinson is making on the value of the x rays in the treatment of leprosy; to improvements in the preparation of cholera and plague vaccine; to researches on glanders and its prevention by Dr. Strone; and to researches on tropical light by Major Woodruff, of the United States army.

New Legal Decisions in Divorce Suits.

An application for divorce recently came before the Supreme Court of Massachusetts based on a complaint of "opium drunkenness." It was alleged by the defence that it was not easy to define the word "drunkenness" as applied to the use of opium, morphine, or other drugs. The court held that the evil effects resulting from the continued use of opium or morphine were well known; they interfered as much with the happiness of married life and produced other effects on the marriage relation as deplorable as those resulting from the excessive use of intoxicating liquors; it was the state thus resulting from their excessive use which the legislature intended to describe by the word "drunkenness" as applied to the use of opium, morphine, and other drugs, and from which it was intended to afford relief to the innocent party. In order to warrant a decree the evidence must be such as to justify a finding that the habit was gross and confirmed and existed when the libel was filed.—An application for divorce came before the Court of *Appeals of Kentucky*, based in effect upon the following question: "Can a wife condone the offence of which the husband confessed he was guilty by living with him, after knowledge on her part of the fact that he had a loathsome disease?" The Kentucky statute declares the "cohabitation as man and wife, after a knowledge of the adultery or lewdness complained of, shall take away the right of divorce therefor." The court in this case placed its opinion on the higher and broader ground that the offence charged in this action is one that the wife cannot condone by cohabiting with her husband so as to deny her the right to obtain from him a divorce for this cause. A husband or wife might be willing and anxious to condone a single act, or a series of acts, of gross misconduct, or cruel treatment, or other specific violation of the marriage obligation, but the infliction of a loathsome disease does not come within this rule; it is a continuing offence, not a distinct or separate grievance that may be forgotten or forgiven in a day or week, or a species of misconduct that affectionate treatment and gentle behaviour might obliterate. It was likely that the defendant when he married believed that he was well, but his innocence in this respect did not affect the question presented. There are reason and justice in the doctrine that the injured spouse may, by his or her voluntary acts, committed with a full knowledge of all the facts, condone a vice or crime, but when either one party or the other has contracted a loathsome disease that may be for all time menacing to the health, dangerous to the life, and distressing to the peace of mind and happiness of the parties, these reasons can have no application.

Effects of Sanitation on West Indian Negro Labourers.

Reports on the health of labourers on the Panama Canal reveal the interesting fact that the sanitary measures adopted for the improvement of the health of the employees have not proved advantageous to the West Indian negroes. They have always been accustomed to sleep in close, unventilated apartments for the purpose of avoiding the night air, which they consider dangerous. The new barracks for labourers admit of very free ventilation night and day, and the result has been that these negroes have been exposed to the night air and the mortality from pneumonia has been excessive.

Fees of Physicians for Insurance Examinations.

The rate of pay of physicians for the examination of persons applying for insurance in life insurance companies has always been disgracefully meagre. The profession has been aroused in many States to the injustice of these fees and there is a widespread movement to obtain redress. The Minnesota State Medical Association has adopted resolutions which declare that any examination for life insurance is incomplete without an examination of the urine of the applicant, and the members of the association are recommended to pledge themselves to charge a minimum fee of $5 for each and every ordinary examination, including chemical there will be opened to its members an "Esposizione Campionaria," an exhibition of specimens of work executed by the blind. Professor Alfonso Neuschüler, President of the organising committee, has by this time received the "adhesion" of well-nigh all the blind asylums and institutions for the industry of the blind throughout Italy—the latter having announced as contributions to the "Esposizione" the most varied and elaborate specimens of the handiwork of their inmates.

Sept. 1st.

CONSTANTINOPLE.

(FROM OUR OWN CORRESPONDENT.)

The Coffee Trade in Turkey.

THE medicinal value of pure and fragrant coffee has long been recognised, and the coffee trade in Turkey may be considered of importance to the whole medical profession. Turkey annually receives from other countries 9,350,458 kilogrammes of coffee of a value of 93,333,278 piastres, and exports only 4,853,423 kilogrammes, representing the sum of 43.876,778 piastres. Of late, the trade in coffee has considerably diminished, due to the fact that the coffee plants of the Yemen plantations have been suffering from a mysterious disease which has not yet been fully and properly investigated. In consequence of this disease the grains become foul and soft inside and very black outside. A short time ago several branches with diseased coffee grains were sent to Constantinople for purposes of examination and chemical analysis. The result of this has not yet been made known. Another reason of the diminution in the trade is the practice of mixing with real coffee all sorts of extraneous matter, sometimes quite harmless, very frequently, however, deleterious to health. A rather usual admixture is the powder of dried figs. The practice of adding the latter to pure coffee is in great vogue not only in Turkey but also in Austria, in certain parts of Germany, in Roumania, and in Servia. Fig powder is added to coffee in the proportion of 1 to 3. The beverage prepared of this mixture has a deeper colour and possesses considerable nutritive qualities, but much of the essential quality of the coffee is, of course, lost.

Syphilis and Venereal Diseases in Sivas.

From several parts of this vilayet the spread of syphilis and venereal diseases is reported. The sanitary inspector of the province has asked the central authorities of Constantinople promptly to adopt all the necessary measures in order to check the propagation of the malady and to treat the sufferers. It is intended to build in Sivas itself a hospital with, to begin with, 50 beds for syphilitic and venereal patients. Two medical men will be appointed, with a salary of 1500 piastres per month. Their duty will be to visit all the contaminated localities and to render gratuitous assistance to all seeking such. They will also receive a proportionate sum for travelling expenses and for drugs and instruments. Similar measures have already been adopted in other provinces. As soon as the authorities in Sivas find the necessary funds the mentioned measures will be executed.

The Exportation of Rose Essence.

The Bulgarian newspaper *Courrier de Sofia* gives interesting details with regard to the export of rose essence from the principality of Bulgaria. According to that newspaper the average of 3011 kilogrammes of rose essence has been yearly exported from Bulgaria during the period of ten years from 1886 to the end of 1895. This represented the annual value of 1,639,754 francs or 544·5 francs per kilogramme. From the beginning of 1889 to the end of 1905 the export gradually rose to the average annual amount of 4150 kilogrammes, representing the sum of 2,749,926 francs, or 662·6 francs per kilogramme. The increase in the last ten years has thus been 1139 kilogrammes, or 27·4 per cent. per year. The income resulting from the export has therefore proportionately increased to 1,100,072 francs, or 40·4 per cent. per year. The essence of roses is exported into almost every country which has commercial relations with Bulgaria. The markets of England, Austria, Germany, Italy, Russia, Turkey, France, and the United States of America are the most stable. The most is exported to the last-named States. Next comes France with 28·8 per cent. Next England with 16·8 per cent. In 1905 the total exportation amounted to 5316 kilogrammes, of the value of 3,712,386 francs.

August 31st.

EGYPT.

(FROM OUR OWN CORRESPONDENT.)

Plague Instructions.

THE management of outbreaks of plague has been a routine part of the duties of medical officers for the past seven years, and it has now been thought advisable to issue in a small handbook a description of the various methods which have been found to work well in practice. The Director-General of the Public Health Department begins by reminding all officers that the same care must be exercised in disinfection and the general management of isolated cases as in dealing with distinct outbreaks. It is this individual care so far exercised in Egypt which has chiefly contributed to the success of anti-plague measures. Directly a living case of plague is discovered a police guard should be placed on the house, and the disinfector and the head man of the quarter must be sent for. The probable source of infection should be ascertained and a list made of all contacts, which includes the inhabitants of the house and the nearest relatives. The patient must be removed to the infectious hospital or to a special building or temporary hut which can be utilised as one. The contacts must be examined every day for ten days and disinfected. If a disinfecting station exists in the town, all clothes and soft goods must be removed there; if not, the clothes must be disinfected with the premises. As soon as possible after the patient's arrival at the hospital some serum should be withdrawn from his bubo (or lung in the case of pneumonic plague) with all aseptic precautions; the drop or two of serum ejected on to agar must be sent to Cairo or Alexandria without delay. When the patient is already dead the specimen for bacteriological examination must be procured in the place where the body is lying, corrosive sublimate, 1 in 1000, is given for washing the corpse, and the shroud must be soaked in the same solution; the bier should be lined with zinc or tin and disinfected after use. It is very seldom found necessary to destroy infected clothes, but they should be soaked in sublimate solution for 20 minutes and afterwards thoroughly dried in the sunlight. In all cases of pneumonic plague the contacts must be kept strictly isolated for ten days. It has been found that when concealment of cases is practised in the village a secret gratuity of one dollar for each report of a fresh case of plague has an excellent effect. In the case of a foreign subject neither disinfection nor removal to hospital can take place without previous consultation with the Consul concerned. When the disinfection of a house is finished all rat holes must be thoroughly opened up, a small quantity of carbolic solution, 1 in 10, poured into them, some broken glass placed so as to plug the bottom of the rat run and held in position by mortar, and the hole mortared up flush with the wall. All dead rats and mice found by the workmen are put into a special paraffin tin and covered with carbolic acid. Rat poisoning is best carried out with phosphorus paste concealed in tomatoes. I may here mention that phosphorus and arsenic are the poisons, together with traps, found most useful in Japan. The number of rats killed in Tokyo since 1900 averages more than 800,000 a year, and it is calculated that these dead rats, laid side by side, would extend for a distance of over 75 miles. Yet according to Kitasato, "we can hardly notice any considerable decrease in the number of these animals in Tokyo." Mosques in Egypt must be treated with respect by the disinfecting gangs, but the manager of the mosque is given sublimate solution so that the mosque servants may carry out disinfection. The most convenient form of hospital hut for rapid building is found to be ten metres long by six metres wide, divided by a partition for the two sexes.

Suppression of Malaria at Ismailia.

Under this title the Suez Canal Company has now published a pamphlet in French with maps and illustrations of mosquitoes, detailing the work done by their medical officers on the recommendation of Major Ronald Ross. The town of Ismailia, founded by Lesseps in 1862 on the borders of Lake Timsah, which is now part of the Suez Canal, is inhabited by some 8000 people. It was considered a very the patient, and that the privilege would be illusory if it were confined to his statement. The court thought that the plaintiff's construction of the section was correct and that the commission must be refused. Cost of the summons would be costs in the cause, as a different construction of the section had prevailed since its introduction. Speaking for himself as to the effect of the decision of the court, one of the judges said the point successfully raised gave new and dangerous effect to the section as an obstruction to the administration of justice. No such obstruction existed in England or, as far as he could ascertain, in any other State of Australia. Since the year 1857 medical evidence had been given without consent of the patient and without objection in innumerable cases in the courts—evidence most important in cases of testamentary or other mental incapacity, in the divorce court as to physical conditions proving infidelity, and in cases such as the one before the court, in which its exclusion might leave fraudulent misrepresentation unexposed. No such evidence could be given in the future without the consent of the patient, which in some cases would not, and in other cases could not, be given. For these reasons it seemed to him that repeal or amendment of the section was urgently called for in the interests of justice.

Secret Medical Preparations.

Under the provisions of the Pure Food Act of Victoria the Board of Health has adopted the following regulations :—

> No compounded drug of which the average dose is more than one teaspoonful (60 minims) for adults, or is more than one-half of one teaspoonful for children under five years of age, unless such compounded drug is a preparation set out in the British Pharmacopœia, or is sold specifically as an alcoholic compound, shall contain more than 10 per centum by volume of ethyl alcohol.
>
> No drug or compounded drug other than any sold specifically as one of, or as containing one or more of the substances set out herein, or *any of their derivations*, shall contain opium, or belladonna, stramonium, nux vomica, cannabis indica, cocaine, heroin, or any derivation of any of these drugs, or chloral hydrate, bromides, sulphonal, trional, veronal, paraldehyde, or any other synthetic hypnotic substance, or phenazonum, phenacetinum, or acetanilidum, or any other allied substance.

Under the Commerce Act of the Commonwealth also the Minister of Customs proposes to include under the regulations the following :—

> In cases where any such article contains not less than 10 per cent. of ethyl alcohol and the average dose recommended for use shall be greater than one teaspoonful (60 minims), or when any such article contains any of the following ingredients :—Morphine, cocaine, heroin, or the salts or derivatives of the same, or any of them, or of chloral hydrate, belladonna, cotton root ergot, or other abortifacient, the description shall contain an intimation to that effect.

Friendly Societies' Dispensaries.

The Prahram United Friendly Societies' Dispensary and Medical Institute has been the defendant in a series of actions recently. The Pharmacy Board of Victoria laid an information that the dispensary not being registered pharmaceutical chemists carried on business as chemists and druggists. The dispensary had established a restricted form of membership whereby members of the public were permitted on payment of a fee of 6*d*. per annum to become "purchasing members" without any other right or privilege except to purchase medicines at the dispensary. The case was first tried by a bench of magistrates who dismissed it. An order to review was granted by a supreme court judge, and the dispensary appealed to the High Court which has now decided against it. The Chief Justice said that if the society were merely dealing with its members in the manner authorised by the Friendly Societies Act it could not be held to be carrying on the business of chemists within the prohibition of the Medical Act, as the two Acts had to be read together. The court was, however, of opinion that the institute was going beyond the mere dealing with its members and was really selling medicines to any of the public who chose to come and pay the necessary 6*d*. and be enrolled.

Hospital Affairs.

A deputation recently waited on the Chief Secretary of New South Wales to ask that legislation should be introduced to prevent other institutions collecting on the same day as the Hospital Saturday Fund and to provide for the proper distribution of all street collections. The Chief Secretary agreed with the deputation and promised to submit a proposal to the Cabinet.—At the last meeting of the directors of the Royal Prince Alfred Hospital, Sydney, a scheme was approved for the allocation of the 469 beds in the hospital when the new wards are opened. The two new pavilions are [illegible]clusively for surgical cases and one 32 bed ward is to be held in reserve to provide for cleaning of other wards and emergencies.—St. Margaret's Hospital for Women, Sydney, has just opened a district nursing branch to provide poor patients with skilled nursing in their own homes and to teach the poor the elements of sanitation in the home. St. Margaret's is a purely private enterprise, founded in 1894 by Mrs. Abbott. It began with two beds, while last year the number of cases attended to was 398 and the number of nurses trained was 26; 23 surgical operations were performed and 33 medical cases were treated in the patients' own homes; 106 surgical operations were performed and 39 medical cases were treated in the hospital; and over 1200 patients consulted the honorary medical staff for diseases of women. Since it began it has paid no salaries to anyone. Neither Mrs. Abbott, who acts as matron, nor any of the nurses receive any remuneration. The chief source of revenue is the fees paid by nurses for training.

Death of Dr. Long.

The death is announced of Dr. Mark Henry Long, late of Marrickville, near Sydney. He was educated at New York and the London Hospital, and obtained the M.D. degree of the University of the City of New York and the Licence of the Royal College of Physicians of Ireland. He came to New South Wales in 1884. Dr. Long was a well known numismatist and author of "A Skeleton Catalogue of Australian Copper Tokens."

August 3rd.

Obituary.

FRANKLIN HEWITT OLIVER, L.R.C.P. LOND., L.S.A.

Mr. Franklin Hewitt Oliver, late of Kingsland-road, Shoreditch, died on August 22nd at Springfields, Clapton, in the north-east of London, after an illness lasting for over two years. He was the third son of Alderman J. Oliver, M.R.C.P., J.P., of Maidstone, and was born in 1859. He received his medical training at Charing Cross Hospital where he had a successful career as a student, and in 1883 he took the diploma of L.S.A. In 1887 he was admitted a Licentiate of the Royal College of Physicians of London and succeeded to the practice of the late Dr. Burchell of Kingsland-road. His practice soon became one of the most extensive in the district and included many public appointments. For many years he held the position of chief district surgeon to the Royal Maternity Charity and at the time of his death was also surgeon accoucheur to the City of London Lying-in Hospital, surgeon to the G and H divisions of the Metropolitan Police, and surgeon to the Almshouses of the Honourable Company of Ironmongers, as well as being on the board of the Charity Trustees. He was also honorary medical officer and chairman to the Hoxton and Haggerston branch of the Queen Victoria Jubilee Nursing Association, and the work he did in this connexion will remain as a monument of his untiring energy and enthusiasm. Mrs. Oliver, who survives her husband, is a daughter of the Rev. William Cuff, pastor of the Shoreditch Tabernacle, and is left with two children. The funeral took place on August 25th at Abney Park Cemetery when on every side there was evidence of the genuine respect in which the deceased gentleman was held.

THOMAS PONSFORD CANN, M.D. DURH.

A SAD instance of the risks incidental to medical practice is supplied by the death of Dr. T. P. Cann of Newhaven. On August 15th he and his assistant performed an operation for the removal of a patient's tonsils, after which Dr. Cann remarked that he had pricked one of the fingers of his left hand while using the guillotine. This unfortunate accident set up streptococcal infection which proved fatal on August 27th. At an inquest which was held on the following day at the urban council's office in Meeching-road the jury returned a verdict of death from blood-poisoning the result of a wound on the finger caused while deceased was performing an operation on a patient. Dr. Cann was born in 1875 at Newhaven, being the eldest son of Mr. Thomas Martyn Cann, who was for many years in medical practice there until his death last June. Dr. Cann studied medicine at the University of Durham and in analysis of the urine, and a minimum fee of $10 for each and every examination where a microscopic examination of urine, sputum, or other secretion is required.

A Proposed National Public Health Society.

The Medical Society of the County of New York announces a convention for the purpose of organising a national society the object of which shall be to enforce laws against the irregular practice of medicine and the adulteration of foods. The recent exposures of the beef trust, the indiscriminate sale of alcohol and narcotics and dangerous poisons under the name of patent medicines, and the alarming conditions made known by the Pure Food Bill have led a great many philanthropists and religious associations to issue a call for a conference to be held in New York on Nov. 15th, to discuss ways and means of organising a society to obtain and disseminate accurate information concerning practices and conditions dangerous to the public health and morals, and to prevent quackery, criminal practices in the healing art, adulteration of drugs, and the sale of narcotics and alcohol under the guise of proprietary medicines.

Preventive Work among School Children.

A remarkable effort, aimed at the very root of crime, is being made by the Philadelphia Society to Protect Children from Cruelty. Alienists, physicians, and specialists in various diseases have been invited to aid in the work. Every child taken care of by the society must have filled out for him by his parents in consultation with the examining physician a blank in which space is given for the identification and description of many ills. These blanks were prepared by the leading physicians of Philadelphia, Dr. Weir Mitchell being of the number. The physical examination relates to the family history, bodily measurements, expression of the eyes, memory, voice, speech, general appearance, and the condition and history of every part of the body. The mental diagnosis is made on the answers to questions of family and physical history and condition of every part of the body. Thus prepared with a trustworthy chart of the physical and mental tendencies of the child, the society is prepared to apply intelligently the proper remedial and reformatory measures.

August 26th.

NOTES FROM INDIA.

(FROM OUR SPECIAL CORRESPONDENT.)

The Difficulties of Water-supply for Large Cities

THE city of Rangoon must now be added to the list of towns in India troubled about their water-supply. The great Hlawga scheme, which has cost Rs. 46 lakhs will only supply adequately a population of 207,000, while Rangoon has now about 300,000 and the population is increasing rapidly. It is estimated that it will cost another Rs 25 lakhs to increase the supply sufficiently for a population of 340,000. It is stated that provision has so far been made for the rate of only 25 gallons per head daily instead of 40 gallons as required. These troubles in Rangoon have their counterpart in Calcutta and Bombay. In the premier city—the capital of India—it is also proposed by the new scheme to provide a supply of 40,000,000 gallons daily. At present about 27,000,000 are pumped into the city daily but by having more powerful engines greater pressure can be put on and the existing mains will probably be able to convey 32,000,000 gallons. This extra supply means more filters besides pumping plant and will cost nearly Rs. 20 lakhs. I have already advised you of the great scheme for a large overhead reservoir to be erected at the north of the city, which will supply water by gravitation instead of by pumping, as at present, at the four distributing stations in the city itself. It seems, however, that the larger supply of water there is to the city the greater proportionate amount of waste goes on, and the cry is continually heard for more. The waste is enormous and is hardly realised by the authorities. Fortunately for Calcutta, the quality of the water is excellent. The filtered water is only used for domestic purposes, there being a separate supply of unfiltered river water for watering the roads and for flushing purposes. Part of the city has had installed a constant system but the larger part is still subject to intermittency.

The Calcutta Crematorium.

The Calcutta Crematorium, after extended trials, has been recently declared fit for use and the first cremation took place a few days ago. The furnace is the patent of Toisul, Fudet, and Co. of Paris, and is worked by gas. The pressure to supply the gas at the rate of 3000 cubic feet per hour if necessary is obtained by a mechanical blower, but it is found that from 6000 to 8000 cubic feet are sufficient for a cremation, and a large part of this amount is consumed in heating up the furnace preparatory to the cremation. I hear that the charges laid down by the corporation are very moderate. There is a growing opinion in favour of cremation in India, and the reduction of the enormous charges at present ruling in connexion with burial will materially promote its more general adoption. This crematorium is the only one worked by gas east of Suez, the other installations at Shanghai employing coke. The gas furnace is perhaps more expensive, but it is certainly cleaner and is devoid of the appearance of a foundry. Although the corporation of Calcutta has liberally provided this crematorium, the credit for its establishment belongs to the Cremation Society of Bengal, which was formed for the purpose and is very influentially supported.

The Plague Mortality.

The plague mortality throughout India, which attained a minimum record for the last week in July, has since increased and the increase has been general in all the districts affected. The figures are small—the total for the week ending August 4th amounting to 738 deaths—but the signs are ominous. The increase in Burmah is especially marked, and Rangoon is probably doomed to another outbreak. Nothing has been announced concerning the researches of the Plague Commission and the old *laissez faire* policy of administration still continues. The only place where a separate plague department seems to be maintained is at Calcutta and the excellence of its work is said to be the chief reason for not placing the administration in other hands.

The High Death-rate in Bombay.

It is a curious thing that while plague is now comparatively quiescent the mortality in Bombay city should be so high, while that of Calcutta is unusually low. The deaths in Bombay may be said to be unaccounted for, because under the heading of "all other causes" the mortality is nearly double the average. A death-rate of from 50 to 60 per 1000 in the absence of an epidemic to explain it requires a searching investigation. It would appear that the first thing Bombay has to do is to find out from what the people are dying. The weekly returns absolutely fail to explain the high mortality.

August 17th.

AUSTRALIA.

(FROM OUR OWN CORRESPONDENT.)

Professional Secrecy.

THE Full Court of Victoria recently gave an important decision as to the interpretation of the law respecting medical evidence. An insurance company was sued for the amount of a policy. The company's defence was that the policy had been secured by misrepresentation, the deceased having stated that he had never had any serious illness, whereas it was asserted that a medical man (not the examiner of the company) had found that he was suffering from pulmonary tuberculosis. The company applied to have this practitioner's evidence taken on commission. The plaintiff objected on the ground that the medical practitioner would be prohibited from giving evidence by a clause in Section 55 of the Evidence Act, 1890, which ran :—

> No physician or surgeon shall, without the consent of his patient, divulge in any civil action or proceeding (unless the sanity of his patient be the matter in dispute) any information which he may have acquired in attending the patient, and which was necessary to enable him to prescribe or act for the patient.

In answer to this objection it had been contended that the prohibition was confined to communications made to the medical adviser by the patient and that he might disclose in evidence any information which he had acquired by his own observation. This contention was supported by the association of this clause with another clause in the same section protecting confessions made to a priest. For plaintiff it was contended that the word "information" was wide enough to cover knowledge howsoever acquired, whether from medical examination or from statements by

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to The Lancet *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.*

Cox, L. J. H., M.B., B.S. Lond., M.R.C.S., L.R.C.P., has been appointed Resident House Surgeon at St. Thomas's Hospital.

Cunningham, A. B., M.R.C.S., L.R.C.P., has been appointed Resident House Physician at St. Thomas's Hospital.

Dickson, A. N., M.R.C.S., L.R.C.P., has been appointed Resident House Physician at St. Thomas's Hospital.

Dunkley, [illegible], M.B., B.S. Lond., M.R.C.S., L.R.C.P., has been appointed House Physician to Out Patients at St. Thomas's Hospital.

Gamlen, R. L., M.R.C.S., L.R.C.P., has been appointed House Surgeon to Out Patients at St. Thomas's Hospital.

Gerrard, Laurence, M.R.C.S. Eng., L.R.C.P. Lond., has been appointed Medical Officer of the No. 9 District of the Lincoln Union.

Harper, Frances Margaret, M.B., Ch.B. Edin., D.P.H. Camb., has been appointed Lady Assistant Medical Officer to the County Borough of St. Helens, Lancashire.

Hewett, F. S., M.R.C.S., L.R.C.P., has been appointed Resident House Surgeon at St. Thomas's Hospital.

Hooker, A. W., M.B., B.S. Lond., M.R.C.S., L.R.C.P., has been appointed Junior Casualty Officer at St. Thomas's Hospital.

Howarth, W. G., M.B., B.C. Cantab., M.R.C.S., L.R.C.P., has been appointed Resident House Surgeon at St. Thomas's Hospital.

Howitt, A. B., M.B., B.C. Cantab., M.R.C.S., L.R.C.P., has been appointed Resident House Surgeon at St. Thomas's Hospital.

Jordan, Alfred C., M.D. Cantab., has been appointed Medical Officer to the Electrical Department of the North Eastern Hospital for Children, Hackney-road.

MacDonald, S. G., M.B., B.C. Cantab., M.R.C.S., L.R.C.P., has been appointed House Surgeon to Out Patients at St. Thomas's Hospital.

Nicholls, Frank J., M.B., B.C. Cantab., M.R.C.S., L.R.C.P. Lond., has been appointed Medical Officer to the London County Council Training College, Avery-hill, Eltham.

Norbury, L. E. C., M.B., B.S. Lond., M.R.C.S., L.R.C.P., has been appointed Senior Casualty Officer at St. Thomas's Hospital.

Page, C. M., M.B., B.S. Lond., M.R.C.S., L.R.C.P., has been appointed House Surgeon to Out Patients at St. Thomas's Hospital.

Philpot, H. A., M.R.C.S., L.R.C.P., has been appointed House Physician to Out Patients at St. Thomas's Hospital.

Sankey, W. O., M.R.C.S., L.R.C.P., has been appointed House Physician to Out Patients at St. Thomas's Hospital.

Sington, H. S., M.R.C.S., L.R.C.P., has been appointed Resident House Physician at St. Thomas's Hospital.

Squires, H. C., M.B., B.Ch. Oxon., M.R.C.S., L.R.C.P., has been appointed Resident House Physician at St. Thomas's Hospital.

Stocker, Edward Gayer, L.R.C.P. Lond., M.R.C.S. Eng., has been appointed temporary Medical Officer and Public Vaccinator for the Clevedon District, Somerset, by the Long Ashton Board of Guardians.

Taylor, Clifford J., F.R.C.S. Edin., has been appointed House Surgeon to the Herefordshire General Hospital.

White, George F., M.D. Dub., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Stanford-le-Hope District of the county of Essex.

Whitehouse, H. B., M.B., B.S. Lond., M.R.C.S., L.R.C.P., has been appointed House Surgeon to Out Patients at St. Thomas's Hospital.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

Ancoats Hospital, Manchester.—Resident House Physician. Salary £80 per annum, with board, residence, &c.

Birmingham Asylum, Rubery-hill.—Assistant Medical Officer. Salary £150 per annum, with apartments, board, &c.

Birmingham and Midland Eye Hospital.—Senior House Surgeon. Salary £80 per annum.

Brighton, Sussex County Hospital.—Second House Surgeon, unmarried. Salary £60 per annum, with board, residence, and washing. Also House Surgeon, unmarried. Salary £100 per annum, with board and residence.

Camberwell House Asylum.—Second Medical Assistant Officer, unmarried. Salary £150, rising to £200, with board, apartments, and laundry.

Cambridge, Addenbrooke's Hospital.—Assistant House Surgeon. Salary at rate of £50 per annum, with board, residence, and laundry.

Cancer Hospital, Fulham-road, London, S.W.—Senior House Surgeon. Salary £80 per annum.

Cape of Good Hope, Grey Hospital, King William's Town.—Resident House Surgeon, unmarried. Salary at rate of £300 per annum, with quarters and one ration.

Cardiff Union Workhouse.—Assistant Medical Officer, unmarried. Salary £130 per annum, with rations, apartments, attendance, and washing.

East London Hospital for Children and Dispensary for Women, Shadwell, E.—House Surgeon for six months. Honorarium of £25, with board, residence, &c.

Eccles and Patricroft Hospital.—House Surgeon, unmarried. Salary £70 per year, with board, residence, and washing.

Egyptian Government, Ministry of Education.—Professor of Midwifery and Gynæcology. Salary £400 a year. Also Medical Tutor and Registrar to Kasr-el Ainy Hospital. Salary £400 a year.

Glasgow, Royal Hospital for Sick Children.—Resident House Physician and Resident House Surgeon, both for six months. Salaries at rate of £50 per annum, with board and laundry. Also Assistant at Dispensary (non-resident) for six months. Salary at rate of £100 per annum.

Great Northern Central Hospital, Holloway.—Pathologist and Curator. Salary £100 per annum. Also Senior House Physician, Senior House Surgeon, Junior House Physician, and two Junior House Surgeons. All for six months. Salaries of senior officers at rate of £50 per annum and of junior officers at rate of £30 per annum, with board, lodging, and washing.

Hastings, St. Leonards, and East Sussex Hospital.—House Surgeon, unmarried. Salary £75 per annum, with residence, board and washing.

Huddersfield Infirmary.—Junior House Surgeon. Salary £50 per annum, with board, residence and washing.

Hull, Victoria Children's Hospital, Park-street.—House Surgeon. Salary £80 per annum, with board and laundry. Also Assistant House Surgeon. Salary £[illegible], with board and laundry. Both females.

Newcastle-on-Tyne, graduating as M.B. and B.S. in 1899. In 1901 he took the degree of M.D. and joined his father in practice at Newhaven. In 1902 he married the eldest daughter of Mr. Henry M. Langdale, a well-known surgeon practising in Uckfield. The deceased was medical officer of health of the Newhaven urban and port sanitary authority. He also held a variety of local appointments, including that of Admiralty surgeon and agent. The funeral took place on August 30th at Bishopstone churchyard and was very largely attended. A carrying party furnished by the detachment of the Royal Army Medical Corps stationed at Newhaven took the body into the church and afterwards conveyed it to the final resting-place.

RICHARD DAVID EVANS, M.R.C.S. ENG., L.R.C.P. LOND.

Mr. R. D. Evans of Llandilo, Carmarthenshire, died at his residence there on August 5th, after a few days' illness, at the early age of 42 years. He received his medical education at St. Mary's and Guy's Hospitals and took the qualifications of the English Conjoint Board in 1894. He had been in practice in Llandilo for some years and was not long ago appointed medical officer of the urban district of Llandilo in succession to the late Mr. W. H. Lloyd. He was also surgeon to the 1st Volunteer Battalion of the Welsh Regiment. Mr. Evans was an able, conscientious, and painstaking practitioner, who enjoyed the confidence of a large circle of patients and friends. He has left a widow and family.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. Nina Rodrigues, professor of forensic medicine in the University of Bahia.—Dr. Philipp Dospranikoff, professor of anatomy in the Military Medical Academy, St. Petersburg.—Dr. Felix Rymowicz, professor of ophthalmology in the University of Warsaw.—Dr. Guyot, senator for the Rhone.—Dr. Salvatore Tomaselli, professor of clinical medicine in the Catania School of Medicine.

Medical News.

FOREIGN UNIVERSITY INTELLIGENCE.—*Berne:* Dr. Loeb has been recognised as *privat-docent* of Pharmacology.—*Budapesth:* Dr. Wilhelm Leitner has been recognised as *privat-docent* of Ophthalmology.—*Florence:* Dr. Lorenz Borri of Modena has been appointed Extraordinary Professor of Forensic Medicine.—*Göttingen:* Dr. Lochte of Hamburg has been appointed Extraordinary Professor of Forensic Medicine. The title of Professor has been granted to Dr. Franz Schieck, *privat-docent* of Ophthalmology.—*Gratz:* The title of Extraordinary Professor has been granted to Dr. Wilhelm Scholz, *privat-docent* of Internal Medicine, and to Dr. Fritz Hartmann, *privat-docent* of Mental Diseases. Dr. Hermann Pfeiffer has been recognised as *privat-docent* of Forensic Medicine.—*Strasburg:* Dr. Franz R. Wollenberg of Tubingen has been appointed to the chair of Mental Diseases in succession to the late Dr. Fürstner.—*Vienna:* Dr. Karl Hochsinger has been recognised as *privat-docent* of Children's Diseases.—*Yale:* Dr. George Blumer has been appointed to the chair of Medicine in succession to the late Dr. Ely.

WEST AFRICAN MEDICAL STAFF.—The following appointments have been made to the West African Medical Staff:—A. N. de Gruchy, M.B., Ch.B. Edin., Southern Nigeria; H. E. Arbuckle, M.B., Ch.B. Edin., D.P.H., Sierra Leone; E. J. Tynan, F.R.C.S. Irel., D.P.H., Southern Nigeria; J. Cross, M.B., Ch.B. Glasg., Southern Nigeria; H. T. Palmer, M.R.C.S. Eng., L.R.C.P. Lond., Gold Coast; W. M. Wade, M.B., Ch.B. Dub., Gold Coast; and A. B. Tighe, M.B., Ch.B., B.A.O. Dub., Gold Coast. The following promotions are announced:—A. H. Hanley, C.M.G., F.R.C.S. Irel., deputy principal medical officer in Southern Nigeria, to be principal medical officer in Sierra Leone, vice W. T. Prout, C.M.G., retired. F. G. Hopkins, M.B., B.Ch. Lond., senior medical officer in Southern Nigeria, to be deputy principal medical officer, vice A. H. Hanley, C.M.G. R. J. D'Arcy Irvine, M.B., M.S., senior medical officer, Gold Coast, retires on pension. G. J. Rutherford, M.R.C.S. Eng., L.R.C.P. Lond., senior medical officer, Southern Nigeria, is transferred to the Gold Coast, *vice* R. J. D'Arcy Irvine.

DISEASED MEAT AT BRISTOL.—The chief inspector of the health department of the Bristol corporation reports that during 1905 the quantity of meat destroyed as unfit for food exceeded 32 tons.

VACCINATION GRANT.—Dr. Alec Forsyth, of Chacewater, Devon, has been awarded for the second consecutive time the Local Government Board grant for successful vaccination.

NEW WORKHOUSE INFIRMARY FOR PLYMOUTH.—At a meeting of the Plymouth board of guardians held on August 21st a tender of £31,637 was accepted for the erection of a new workhouse infirmary.

CONVALESCENT HOME FOR NEWPORT.—Lord Tredegar has given property valued at £12,000 near Newport (Mon.) for the erection of a convalescent home, which will be also fitted up at his expense.

MANCHESTER EPILEPTIC COLONY.—A new epileptic colony for Manchester was formally opened on Sept. 3rd by the Earl of Derby, Lord Lieutenant of the county. The site of the colony is at Langho and the buildings will provide accommodation for over 270 patients, together with the necessary offices and staff. The buildings are divided into separate blocks, each planned to contain 40 beds. Altogether the buildings at present erected number 16, including the house of the medical superintendent, an administration block, a reception and hospital block, the central kitchen and stores block, a general laundry, and workshops for various trades. The ceremony was attended by the Lord Mayor of Manchester and a large number of municipal authorities of the county and district. The visitors assembled in the hospital ward and then walked in procession to the front entrance of the administrative block, where Lord Derby was given a gold key with which to unlock the door. The Rev. J. A. Rushton read prayers in conclusion of the ceremony, and luncheon was afterwards served in the Assembly Hall under the presidency of Dr. J. M. Rhodes, the chairman of the Chorlton and Manchester joint asylum committee.

GRIMSBY TOWN COUNCIL AND THE MEDICAL OFFICER OF HEALTH.—On August 29th a special meeting of the town council of Grimsby was held to consider the question of the appointment of a medical officer of health in succession to the late Dr. T. Newby. The meeting was presided over by the mayor. A long argument ensued as to the desirability of making a temporary appointment or not, and the feeling of the meeting in general evidently was that, in place of the present system in which the medical officer of health had been allowed to take private practice and under which various medical men performed various public duties it, would be better to have a medical officer for all public work in the borough, who should give up the whole of his time to his official duties. Sir George Doughty, M.P., however, apparently took exception to this view. Finally it was decided to advertise for a medical officer at a salary of £500 per annum who would undertake all corporation work except that of the education committee. The mayor remarked that he thought £500 was too small a salary, but it does not appear from the report that any increase was voted.

BOOKS, ETC., RECEIVED.

BRYCE, DAVID, AND SON, Glasgow.

e could dismiss the case, allow him to withdraw it, or grant an djournment in order that further medical evidence could be given.

Mr. Baggallay said that in his opinion the society commenced hese proceedings too quickly. The child had already undergone our operations and the mother was not satisfied that another was eally necessary. The mother was entitled to know from a specialist hat a fifth operation was essential. In the circumstances the ummons would be dismissed.

Mr. Jenkins: If you want any further medical evidence it shall e produced.—Mr. Baggallay: I have heard the whole of the evidence ou chose to produce and the case is dismissed. I am not the rosecutor.

Mr. Sydney: I do not know what you will say in regard to costs. My client is a poor woman and she has been brought here at considerable expense, which she cannot afford. Mr. Baggallay: If I allow costs it will be rather assuming that I think the mother is entirely right. I do not, but I think the society is wrong in taking these proceedings so hurriedly.

A QUESTION OF LEGAL PROCEDURE.

n interesting question has arisen at Hinckley. It seems that the relieving officer gave an order for medical attendance to a man in the town, the order being addressed to Dr. A. W. Jenkins, the medical officer appointed by the urban district council. Upon examining his patient Dr. Jenkins found it would be necessary to amputate one of the man's legs, and ordered his removal to the Cottage Hospital, to which the Hinckley guardians subscribe annually. Upon this coming to the notice of the medical officer of the workhouse he contended that as the guardians would have to pay for the amputation the patient should have been brought to the workhouse infirmary, where he would have performed the operation. Both medical men put their views before the guardians, but in the meantime Dr. Jenkins amputated the limb at the hospital. We are glad that we are not asked to express an opinion upon the matter; it bristles with legal points.

A QUESTION IN PHARMACY.

To the Editors of THE LANCET.

SIRS,—In Whitla's "Pharmacy, Materia Medica, and Therapeutics" of an old date, 1892, he says under Chrysarobin (p. 363), "Brooke's Salve Sticks are a splendid way to use chrysarobin." I have tried to get these through my druggists in London and have not succeeded. Can you help me in this matter?

I am, Sirs, yours faithfully,
FRANK HOWARD,
Sept. 2nd, 1906. Colonel, Army Medical Staff (R.P.)

*** We do not know the particular preparation referred to by Sir William Whitla, but the Pharmacopœia of St. Mary's Hospital, London, contains the following which is probably very similar: "'Baculum chrysarobini:' chrysarobin, 3; wax, 2; lanolin, 5."—ED. L.

MEDICAL MAN AND SPIRITUALIST.

IT is not often that spiritualistic phenomena are in evidence at a coroner's inquest but such a case occurred the other day in Manchester during an inquiry concerning the death of an infant. It died from "accidental suffocation following convulsions." A juror asked Mr. W. J. Heslop, who had examined the body, if he found any impression near the mouth as if it had been covered by an arm or anything like that, to which the reply was that there was no impression at all. The juror claimed to be a spiritualist and clairvoyant, and said he could see a mark on the chin. Mr. Heslop said he was afraid that was not evidence, but the juror persisted, saying: "You may laugh, but it is so. I can see a mark on the chin." A verdict of "Death from natural causes" was returned.

FLOWERS FOR TOWN-DWELLERS.

IT has been recognised in all our hospitals that the keeping of the wards bright with flowers and foliage is particularly grateful to patients. "The spleen is seldom felt where Flora reigns," said the poet, and it seems as though the unrolling of the frond or the development of the bud awakens in the sick thoughts of hope, life, and health. But there is no reason why the beneficial influences of Flora should be restricted for town-dwellers to the time of sickness, although this is practically the only time when they get the solace of leaves and flowers. The majority of us may be compelled to live in the smoke-laden air of a large town, made the more disagreeable nowadays by the fumes of petrol, and the number of persons now driven into towns, as the only centres of employment, is getting larger daily, but the amount of vegetation that will thrive in towns is hardly appreciated. In a recent article in the *Times* a writer advocated the cultivation in garden, forecourts, residential dwelling rooms, and in the dreary, and ofttimes grimy, surroundings of offices and other places of business, of some of our native hardy ferns, which he believed would readily adapt themselves to conditions under which flowering plants would sicken and die. There is no doubt that much might be done in this way to beautify some of the dreary homes and streets of our towns, and the question is a practical one because there are fortunately many other plants besides ferns which could be used for this purpose. This was admirably demonstrated by the Country in Town Exhibition held at Whitechapel in July last and briefly commented upon in our columns (*vide* THE LANCET, July 14th, p. 135). We cannot change our busy commercial centres into garden cities but we can do a great deal towards beautifying them and making them more healthy by calling to our aid plants and flowers. For some years the larger thoroughfares in London have been planted with trees—indeed, it is surprising how difficult it is to get out of sight of a tree in London—and here and there plants may be found in window-boxes or in tubs at the doors of business premises. But if a few more exhibitions such as that at Whitechapel were held the mind of the public would awaken to possibilities undreamed of in the past except by the few. Meanwhile, let us welcome every suggestion for the making of London beautiful and healthy. By the way, we may add that we do not advocate the denuding of lovely country spots of ferns and flowers that they may be sold in the towns, there to die of unsuitable attempts at culture. There are common and hardy plants enough and to spare, and anything like defilements of the country side is odious.

THE HUMOURS OF COUNTRY PRACTICE.

To the Editors of THE LANCET.

SIRS,—In a recent issue of THE LANCET you gave several amusing instances of the various humorous occurrences, both written and spoken, of country practice and I venture to send you a few copied *literatim* from my collection. I regret that it is impossible to reproduce the original writing, but it is of about equal merit with the spelling. The first one is from an old gentleman who evidently believed in President Roosevelt's spelling reform.

> "Pleas send me another botle of medson and sstivicate for another fortnit for the club."

An alternative spelling of certificate is as follows:—

> "Sir—Will you be so kinde as to send my son's cifictat and oblig."

A representative note describing a patient's condition is as follows:—

> "Mr. —— is a litl betr o as ad a betr nit."

The diagnosis in the following is excellent:—

> "Sir Pleas send me a bottel of medisen for the influne and New Ralge by post."

A genteel note to tell of a fortunate occurrence from the patient's point of view reads:—

> "Sir—J. T. R—— has ad a sattisfactrey moshon."

Erysipelas proves a great stumbling block, as the two spellings here given show conclusively:—

> "Plese will you send me sum medsen I think I have gott Hair Sipless I got a lot of spot hon my fase."

> "Dear Sir Sorry to say that my face is not any better and I am afraid it is turning to Harrysiplice."

This description of a hysterical attack, if not as comprehensive as that in the textbooks, is very graphic:—

> "Docker If you pleas betsy Ann she as som verry bad pains in her legs and thay swell and her stomak is so bad we pain in a moring that she scars can walk and all most fants a way then she borst out crine and she so low spert and pleas will you grant her a medual certifiate Mr. —— sent to me for won from henery S."

The delicacy underlying the bracketed information in this letter is delightful:—

> "I have not been well of late so much pain across my loins, shoulders left side & very much on left on top of body I am (3 mths Fragrant) & a lot of bearing down pains."

This is a happy effort:—

> "Sir please my husband mends slowey of is exmas."

The writer of this letter is still alive:—

> "From Mrs ——
> "To the docker I ham sorry to say my Left side is so bad it is like sumthing pulling and narling and tearing from my shoulder blade down to my waste so giddey up my neck to the crown of my head I carsley can gide my self a bout dow you think docker if I had sumthing to rub it with outside it wood dow me any good my ribs hurts me so yours truly."

The last I will give is a letter from a lady asking for a school certificate as the children "had the girmen miseals and will you please send me a cerstificate."

I inclose my card and remain, Sirs, yours faithfully,
Sept. 1st, 1906. RUSTICUS.

THE USE OF GOAT LYMPH IN BRIGHT'S DISEASE.

To the Editors of THE LANCET.

SIRS,—I should be grateful if any of your readers could give some information on the above subject. My own knowledge exceedingly meagre and anything in the way of criticism will be acceptable. So far I am prejudiced against its use, both on the intolerable thirst produced and the occurrence of muscular ability. Before going further into the subject I should be gl know the opinion of others on the use of the lymph in the question.

I am, Sirs, yours faithfully,
August 29th, 1906. A GENERAL PRACTIT

LEICESTER INFIRMARY.—House Physician and Assistant House Physician. Salaries at rate of £100 and £50 respectively, with board, lodging, and washing.

LEICESTER, PARISH OF.—Resident Assistant Medical Officer. Salary £120 per annum, with rations, apartments, and washing.

LIVERPOOL INFIRMARY FOR CHILDREN.—Assistant House Surgeon for six months. *Salary £30, with board and lodging.*

LIVERPOOL, ROYAL SOUTHERN HOSPITAL.—Resident Pathologist and Registrar. Salary £100, with board and residence.

LOWESTOFT HOSPITAL.—House Surgeon, unmarried. Salary at rate of £80 per annum, with board, lodging, and washing.

MACCLESFIELD GENERAL INFIRMARY.—*Junior House* Surgeon. Salary £60 per annum, with board and residence.

MANCHESTER, UNIVERSITY OF.—Junior Demonstrator in Physiology. Salary £100, rising to £150 per annum.

METROPOLITAN HOSPITAL, Kingsland-road, N.E.—House Physician, House Surgeon, Assistant House Physician and Assistant House *Surgeon, all for six months. Salaries of two former at rate of £40* a year and of two latter at rate of £20 a year. Also Casualty Officer. Salary at *rate of £150 per annum.*

NEWHAVEN URBAN AND PORT SANITARY AUTHORITIES.—Medical Officer of Health. Salary *£75 per annum.*

NORTHAMPTON GENERAL HOSPITAL.—Assistant House Surgeon. Salary £50 a year, with apartments, board, washing, and attendance.

PENDLEBURY, MANCHESTER CHILDREN'S HOSPITAL.—Assistant Medical Officer. Salary £100 per annum.

READING, ROYAL BERKSHIRE HOSPITAL.—House Surgeon. Salary £80 *per annum, with board, lodging, and washing. Also* Assistant House Surgeon. Salary £60 per annum, with board, lodging, and washing.

ROYAL LONDON OPHTHALMIC HOSPITAL, City-road, E.C.—Senior House Surgeon. Salary at rate of £100 a year, with board and residence.

SHEFFIELD ROYAL HOSPITAL.—Resident Medical Officer, unmarried. Salary £50 per annum, with board and lodging.

SHEFFIELD UNION HOSPITAL.—Resident Medical Officer. Salary £100 per annum, with apartments, rations, and allowances.

SOUTHAMPTON, FREE EYE HOSPITAL.—House Surgeon. Salary £150 inclusive.

VICTORIA HOSPITAL FOR CHILDREN, Tite-street, Chelsea, S.W.—House Surgeon for six months. Honorarium of £25, with board and lodging.

WEST LONDON HOSPITAL, Hammersmith-road, W.—Two House Physicians and Three *House* Surgeons for six months. Board, lodging, and laundry provided.

Births, Marriages, and Deaths.

BIRTHS.

ARCHDALL.—On August 25th, at 42, Ashburnham-road, Bedford, the wife of Mervyn T. Archdall, L.R.C.P., L.R.C.S., *of a daughter.*

ARMSON.—On August 18th, at The Moat, Yoxall, Burton-on-Trent, the wife of Frank G. Armson, M.R.C.S., L.R.C.P., of a son.

BOWER.—*On August 28th, at* Viewfield, Stretton, near Warrington, the *wife of H. E. Bower, M.D.,* of a daughter.

BUTTERWORTH.—On August 29th, at The Crescent, Wisbech, the wife of Rupert Butterworth, B.A., M.B., B.C. Cantab., of a daughter.

GORDON-GREEN.—On September 1st, at Westerton, 46, Beach-road, Southsea, the wife of Staff-Surgeon H. W. Gordon-Green, R.N., *of a* son.

WINDSOR.—On August 31st, the wife of Charles William Windsor, M.D., of a son.

MARRIAGES.

ANNAND—*RANNIE.—At Marlborough-place* Church, N.W., on the 29th August, William *Fraser* Annand, M.D., son of R. C. Annand, of Harton *Lea, South Shields, to Jessie,* daughter of the Rev. J. Rannie, late of Berbice, British Guiana. At home, 9, Lichfield-road, Stafford, after *October 15th.*

COLLIER—SUMMERHAYES.—On Sept. 1st, at All Souls, Langham-place, James *Stansfield Collier, M.D., F.R.C.P., second son of Alfred* Henry Collier, Esq., of Cranford, Middlesex, to Minna Maud, only daughter of William Summerhayes, M.D., of Loyterton, Beckenham.

GAYNER—EDWARDS.—*On* August 28th, at the Friends' Meeting House, Isleworth, John *Stansfield Gayner, M.R.C.S., L.R.C.P. Lond.,* to Alice Maud, daughter of the late Edwin Edwards.

LATHAM—LARSEN.—On *August 23rd,* at the Cathedral, Trondhjem, Norway, Arthur C. Latham, M.D. Oxon., *to* Ella Augusta Petrea Larsen, daughter of the late Herr Peter Larsen.

LONGSTAFF—*DONALD.—On August 29th,* at All *Saints,* Bolton, Mealsgate, George Blundell Longstaff, M.D., to Mary Jane, daughter of the late Matthewman *Hodgson* Donald.

DEATHS.

SIMPSON.—*On August 28th, at Diyatalawa,* Ceylon (Naval Camp), of enteric, Herbert Bartlett Simpson, M.R.C.S., L.R.C.P., Surgeon, R.N., *H.M.S. Sealark, dearly* loved eldest son of George Bartlett and Ellen Simpson, of 2, Chepstow Mansions, W., in his 29th year. *(By cable.)*

WHITAKER.—On August 29th, at White *Lodge, Shrewsbury, Edmund* Thomas Whitaker, M.B., B.Sc., D.P.H., Barrister-at-Law, M.O.H. for the county of Montgomery and *other districts,* elder son of the late Dr. Edmund Whitaker, J.P., Bacup, Lancashire.

WHITE.—On Sunday, August 26th, at Victoria Hospital, Folkestone, *Richard Dormer* White, M.A., M.D. Univ. Dub., Deputy Inspector-General of Hospitals and Fleets, Royal Navy, aged 61. Interred at Brompton Cemetery August 30th.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

THE PREVENTION OF CRUELTY TO CHILDREN ARISING OUT OF NEGLECT OF MEDICAL ADVICE.

AT *Tower Bridge police-court on August 31st Caroline Russell, of* 7, Wickham-place, Tabard-street, Borough, was summoned before *Mr. Baggallay by the National Society* for the *Prevention of Cruelty* to Children for neglecting her son Robert, aged eight years. Mr. *Huntley Jenkins appeared for the* society and Mr. Sydney defended. Mr. Jenkins said the *case* was not an ordinary one of neglect and *it raised* a somewhat unusual point. Shortly put, the case was that there was medical evidence to show that an operation upon the boy was absolutely necessary and the defendant in opposition, if not defiance, declined *to* have it *performed.* The *secretary* had *no* vindictive feeling and there was no neglect in the ordinary sense, the defendant being a *fond* and careful mother. She was a *married woman* but *her husband* was a soldier abroad. The child first came under the notice of the society last December. He was then a cripple and the defendant stated that the *child* had been *operated on* three or four times at Guy's Hospital and that since that time she had taken him to a Mr. Burgess. The *boy was kept under observation,* and on August 10th the defendant consented to the child being examined by *a medical man on behalf of the society. The examination was made* by Mr. E. MacDonald Judge, and on August 13th the society's officer, Mr. *Lodge,* read *to* the defendant the medical man's certificate, which stated that the boy was suffering from necrosis of the *left thigh bone* and *in his* opinion surgical interference was absolutely necessary *to save the* limb and possibly the child's life. The defendant still refused to have the operation *performed* and declared her intention of continuing *to use the ointment which she* received from Mr. Burgess, and which she considered was making *the* child better. Mr. Burgess was not a medical practitioner, but there was no complaint against him.

Mr. Lodge, in answer to Mr. Sydney, said that in December the *child could only* walk with the aid of crutches.

Mr. Sydney: *Let* the boy walk across the court.

The boy did so without any artificial aid.

Mr. Baggallay: Are you sure this is the same child?

The Witness: Yes.

You have no doubt about it?—No.

Mr. Judge said that the child had necrosis of the thigh bone in the *lower quarter. He recognised* that the child had been well cared for by the mother who had built up his general condition by intelligent treatment. The *boy* should be under the care of a surgeon and an operation should be performed.

Mr. Sydney: Are you aware that this child has already undergone *four operations?*—Yes.

Do you say operations are *effective in this disease?*—Yes; but sometimes a dozen operations are necessary.

Would not four operations upon a little *child* like this in 12 months be a fair trial?—No.

Did you attempt to ascertain the properties *of* the *ointment* that the woman was applying?—No; ointment is useless in such a case.

Can you say that the application of this ointment was not beneficial?—A corn plaster put on a boot will not cure a corn. The ointment *is* perfectly useless; *it only goes on the skin.*

Last Christmas the child was a cripple. Can you suggest how the child is now able to walk so well unless *it be through the application* of the ointment?—The mother by intelligent treatment has brought about a general improvement *in* his health, but the *disease* of the bone still remains.

In reply to the magistrate the witness said he *did not probe* the leg because he promised the mother not to hurt the boy. He could not positively say that the *disease* was tuberculous, but there was necrosis. *He* would not advise an operation until he had probed. What he meant by "surgical interference" in his certificate was that the child should be placed under the care of an experienced surgeon who would watch him *for a few* days and then operate.

Mr. Baggallay said that before the society had taken proceedings *of this sort* it should have called a specialist in. There was also the fact that the summons was issued *only* seven days after the medical man gave his certificate.

Mr. Jenkins: Because the *woman* flatly refused to take the child to the hospital.

Mr. Baggallay: You want to punish *her because she won't obey?*—Mr. Jenkins: We do not want *her punished.*

Mr. Baggallay: Then what is the *meaning of these proceedings?*—Mr. Jenkins: The *only way we could get* the *custody of the* child to have the *operation performed* was by taking these *proceedings.* We only want a *technical conviction.*

Mr. *Baggallay: I do not* know what a technical *conviction means.*—Mr. Jenkins: Being *bound* over or a shilling fine.

Mr. Baggallay: The *conviction* of the mother for all time of having been guilty of neglecting *her* child!

Mr. Jenkins said the *proceedings* were only taken in the interests of the child. If the magistrate was n

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

THE Index to Vol. I. of 1906, which was completed with the issue of June 30th, and the Title-page to the Volume, were given in THE LANCET of July 7th.

VOLUMES AND CASES.

VOLUMES for the first half of the year 1906 are now ready. Bound in cloth, gilt lettered, price 18*s.*, carriage extra.

Cases for binding the half-year's numbers are also ready. Cloth, gilt lettered, price 2*s.*, by post 2*s.* 3*d.*

To be obtained on application to the Manager, accompanied by remittance.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and not to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.				TO THE COLONIES AND ABROAD.			
One Year	£1	12	6	One Year	£1	14	8
Six Months	0	16	3	Six Months	0	17	4
Three Months	0	8	2	Three Months	0	8	8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and Agents are authorised to collect, and generally do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied. Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND.

During the week marked copies of the following newspapers have been received: *The Times, The Irish Times, Macclesfield Courier, Newcastle Chronicle, Daily News, Scientific American, Literary Digest, Rotherham Advertiser, Western Mail (Cardiff), Birkenhead News, Chelsea Observer, Wakefield Express, &c.*

PRINCIPALS, LOCUM TENENTS, AND MEDICAL AGENTS.

To the Editors of THE LANCET.

SIRS,—During the last 30 years I have acted, in order of time, as locum tenent for about three years, have been a principal for nearly 23 years, am now acting again as locum tenent, and in a few weeks intend to enter on another practice on my own account, so my experience has been varied and extensive. I have engaged gentlemen to act for me as locum tenents and have acted as such myself. First of all, with reference to medical agents and their fees, my opinion both from the principal and locum tenent's point of view is this, that the fairest and most satisfactory offices to deal with are those which charge a uniform fee of half a guinea to each side. The principal who is willing to pay his share of the fee as a rule secures a more trustworthy representative in his absence, while, on the other hand, the agents who do not charge the principal usually take care to exact a larger fee from the locum tenent, especially when the engagement extends to a month or over that period. This system, needless to say, tends to drive many good locum tenents away, only to seek engagements through those offices where the principal pays half the office fee. Writing now as one who has been, and is about to become, a principal again, I may be allowed to say that a trustworthy locum tenent soon knows his worth and how his services have been appreciated and sought after by those he has acted for, consequently he resents having to pay a larger fee than half a guinea (10*s.* 6*d.*) for any engagement, especially when tips to servants in each house and other and not inconsiderable extras, such as the expense of living in hotels in town in the interval between engagements, are taken into consideration.

I am, Sirs, yours faithfully,

Sept. 3rd, 1906. RETROSPECT.

GOVERNMENT STAMPS ON PATENT MEDICINES.

A PARLIAMENTARY return prepared by the Treasury officials shows that in the year ended March 31st, 1906, the gross receipts derived from the issue of stamps for patent or proprietary medicines amounted to £325,103 13*s.* The numbers of stamps issued, varying in rate according to the price of the medicines, were: at 1½*d.* each, 31,322,832; at 3*d.* each, 7,222,432; at 6*d.* each, 1,154,092; at 1*s.* each, 134,357; at 2*s.* each, 14,808; at 3*s.* each, 12,625; total, 39,861,146. In the year 1901–02 the total number of stamps issued was only 37,753,999, and the gross revenue therefrom only £306,456 17*s.* 2*d.*

HOMES FOR EPILEPTICS.

To the Editors of THE LANCET.

SIRS,—Could any of your readers inform me of a home or institution where a woman, aged about 40 years, who suffers from epilepsy would be received at a small weekly charge?

I am, Sirs, yours faithfully,

EUSTACE J. DE GRUYTHER.

621, Seven Sisters-road, South Tottenham, Sept. 4th, 1906.

FIRST AID IN THE POLICE FORCE.

IN committing for trial a prisoner recently charged with maliciously wounding a policeman by stabbing him Mr. Mead commented thus upon the conduct of another constable who had rendered first aid to the injured man: "I must compliment Police-constable Rodgers on the way in which he rendered first aid. The efficient way in which it is rendered by the police is often brought to my notice. It shows how well the police are instructed in the exercise of this aid and how much the public benefit by it." Everyone will be glad that those who instruct the police should be thus congratulated and that the force should be able to make practical use of the instruction imparted, which, must have the effect of awakening their intelligence in many ways. For instance, it no doubt assists them in the appreciation of those cases in which illness is likely to be mistaken for the effects of drunkenness. If there have been instances recently of such mistakes, fewer have been reported in the newspapers, and it is to be hoped that this dangerous error is of less frequent occurrence than it was some years ago. Police-constable Rodgers was able to render effective assistance to a comrade, whose serious condition may be inferred from the fact that he collapsed almost immediately after receiving his wound and from the evidence of a medical witness who deposed that he would be incapacitated for at least a month.

A NEW BED STUFFING.

WE have received from Mr. Thomas Heard of Albert House, Regent-street, Cheltenham, a sample of bedding material which at first sight appears to be cotton wool. On close examination, however, it is found to be of a much finer texture and is quite silky to the touch. Under the microscope the material is seen to consist of small capillary tubes. It is claimed that this material, which we suspect is a vegetable flock akin to thistle down, is very resistant to mildew and to damp and therefore presents very decided advantages as a mattress stuffing compared with many other materials in use. From our examination of the material we can well believe it, and should think that it would make a very excellent bed stuffing. It is soft and silky and yielding. We are disposed to wonder whether any large demand for it could be supplied. We have already referred in our columns to the utter disregard paid to the sanitary condition of material intended for stuffing mattresses, filthy rags being sometimes used for the purpose which have undergone absolutely no cleansing process. If the material of which a specimen has been sent to us by Mr. Heard can be supplied in unlimited quantities and at a moderate price it should have a big future, for it satisfies the requirements of a sanitary and comfortable bed stuffing.

◆

Anonym.—The openings do not appear to us to be very numerous. Application should be made to the Pharmaceutical Society (17, Bloomsbury-square, London, W.C.) and the Society of Apothecaries of London (Water-lane, Blackfriars, E.C.) for information as to the course for the qualifying examinations. The Students' Number of THE LANCET contains the names of certain private schools of instruction.

An Old Shikari.—Our correspondent is thanked for his communication. With regard to his offer we do not think that there will be any benefit in making it public. Extirpation of the spleen is not a particularly difficult operation and no conclusions with regard to the effect of removal of the spleen bringing about immunity from malarial infection or otherwise could be drawn from one case.

ERRATA.—In the list of the medical and surgical staff of Guy's Hospital which appeared in THE LANCET of Sept. 1st, p. 566, the name of Mr. R. C. Lucas should have been added to the list of consulting surgeons. From the list of anæsthetists the name of Dr. D. Forsyth should have been omitted and in the list of medical registrars and tutors the name Mr. H. C. C. Mann should read Dr. H. C. C. Mann.—The Royal Institute of Public Health should have been included in the list of places giving instruction in public health at p. 615 as being a place approved for practical laboratory instruction for the diploma in public health.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

Medical Diary for the ensuing Week.

A Presidential Address

ON

TEN YEARS OF LUNACY TREATMENT IN LEWISHAM INFIRMARY.

Delivered to the Members of the West Kent Medico-Chirurgical Society on May 4th, 1906, at the Miller Hospital, Greenwich, S.E.,

BY F. S. TOOGOOD, M.D. LOND.,
BARRISTER-AT-LAW; MEDICAL SUPERINTENDENT OF LEWISHAM INFIRMARY.

GENTLEMEN,—The question of lunacy and its early treatment has of late occupied so prominent a position in both professional and lay journals that an excuse is scarcely needed for publishing a record which I believe to be unique.

A short history of the origin of the method adopted in Lewisham on my recommendation will help to elucidate a somewhat complex procedure. Until 1894 there had been no separate infirmary in this district. The sick were treated in wards in the workhouse, the nursing was mainly effected by old pauper women under some trained supervision, and the medical officer had also the charge of a large Poor-law district as well as a large private practice. A room in a small cottage capable of holding two beds sufficed for the female lunatics, whilst a dark shed containing four beds accommodated the males. A padded room, damp, with a leaky roof and of a very antique pattern, served for the temporary restraint of both sexes. What happened when a male and a female needed restraint simultaneously I do not know. The institution weighbridge, over which every vehicle entering the workhouse necessarily passed, was situated immediately behind the padded room and its rattle, together with the noise—vehicular, equine, and human—attendant upon its use could scarcely have exerted a soothing influence upon the excited occupant. The lunacy procedure in vogue at that time appears to have consisted in the transfer of the alleged lunatic to an asylum as soon as the necessary certification had been effected. Apparently only those cases were admitted to the workhouse which were too violent to be treated even temporarily at home or where the domestic circumstances demanded immediate removal. Cases falling into the hands of the police as wandering lunatics have always been handed over to the Poor-law authorities at once. The removal of a patient recovering from delirium tremens to the county asylum resulted in a series of grave charges against the management. A Local Government Board inquiry exonerated the officers concerned, but it was generally felt that some change of method was desirable and on my appointment as medical superintendent of the new infirmary in 1894 I found the way clear for the adoption of a plan which I had already instituted in St. George-in-the-East. The system is, briefly, the detention of all cases of alleged lunacy concerning whom the aid of the Poor-law authorities has been invoked for a period not exceeding 17 days in the infirmary. At first I had to make shift with two small wards in the infirmary, allowing four beds for males and seven for females. There was no padded room and yet in the five years which elapsed before the building of the present mental block in only 28 cases was it necessary to use mechanical restraint, which has never exceeded the temporary employment of a long-sleeved jacket whereby the arms are confined to the sides. The movement was heartily supported by the bench of magistrates and notably by Mr. Brownlow Poulter, Mr. William Brown, and more recently by Dr. Ralph Gooding, the Deputy Lieutenant of the county. In 1899 the present mental block was opened. It affords accommodation for 11 male and 11 female cases, with a padded room for each sex.

The provisions of the Act of 1890 are somewhat confused reading, but in practice the working is very simple. The attention of the relieving officer having been called to a case of mental disturbance, he adopts a course of action varying with the financial and mental condition of the patient. If he be technically a pauper (a term which is inclusive and elastic) and he be obviously off his mental balance the relieving officer deals with him under Section 20 and removes him to the infirmary where he is received, relieved, and detained for three days. A non-pauper, if the case be urgent, can be dealt with under this section. Within these three days the relieving officer has to give notice to a justice having jurisdiction in the place (Section 14, Subsection 2) who, upon receiving such notice, shall by order require the relieving officer giving the notice to bring the alleged lunatic before him at such time and place within three days from the time of the notice to the justice as shall be appointed by the order (Section 14, Subsection 3). This is effected by the justice visiting at the infirmary. It will be noticed that although the alleged lunatic can only be detained in the infirmary for three days upon the relieving officer's order, yet this officer has three days in which to give notice to the justice, who in turn can defer the examination for another three days, so if a relieving officer gave his notice to the justice at the end of the time allowed by the Act and if the justice were equally dilatory the patient could claim his discharge two days before the date fixed for his examination. Under Section 16 the justice must call in a medical practitioner and must himself examine the alleged lunatic, and if upon such examination he is satisfied that the alleged lunatic is a lunatic and a proper person to be detained, and if the medical practitioner who has been called in signs a medical certificate with regard to the lunatic, the justice may (permissive, not compulsory) by order direct the lunatic to be received and detained in the institution for lunatics named in the order. Now under Section 19, Subsection 1, a justice making an order for the reception of a lunatic otherwise than upon petition may suspend the execution of the order for such period not exceeding 14 days as he thinks fit, and in the meantime may give such directions for the proper care and control of the lunatic as he considers proper, and it is under this subsection that we detain the majority of our cases. The police have equal powers with the relieving officers but as a matter of practice they only exercise them in the case of lunatics, paupers or otherwise, wandering at large, who although separately dealt with under Section 15 yet are subject to an exactly similar procedure. The case of the non-pauper is dealt with under Section 13, which enacts that every constable, relieving officer, and overseer of a parish who has knowledge that any person within the district or parish who is not a pauper and not wandering at large is deemed to be a lunatic and is not under proper care and control, or is cruelly treated or neglected by any relative or other person having the care or charge of him, shall within three days after obtaining such knowledge give information thereof upon oath to a justice, being a judicial authority under this Act. Under Subsection 2 the justice *may* visit the alleged lunatic but he must direct and authorise two medical practitioners to visit and certify. The justice then proceeds in the same manner and has the same powers as if a petition for a reception order had been presented, and under Section 21, Subsections 1, 2, and 3, the justice in these non-pauper cases may now make an order for taking the lunatic to, and receiving him in, the infirmary for a period not exceeding 14 days. Put tersely, a pauper is taken to the infirmary on the judgment of the relieving officer; he must be seen by a justice and by a medical man and when a reception order to an asylum has been signed for him he may be detained in the infirmary for 14 days. A non-pauper has a statement concerning him made upon oath; he must be seen by two medical men at separate times and if their certificates warrant it the justice may commit him to the infirmary for 14 days. The whole procedure is hedged about by restrictions and safeguards; there is nowadays no danger of sane persons being confined in asylums, but rather that persons who ought to have their liberty restricted are allowed to have full scope to ruin themselves and their families.

Having by a somewhat complicated process succeeded in getting our patient committed to our custody let us analyse the different forms of his insanity and the prospects of his cure. During the ten years from 1896 to 1905, 2033 cases of alleged lunacy have been admitted; of these 1020 were discharged either cured or sufficiently recovered for their friends to look after them, 804 were sent to asylums, and 209 died.

An original and novel feature of "THE LANCET General Advertiser" is a Special Index to Advertisements on pages 2 and 4, which not only affords a ready means of finding any notice but is in itself an *additional* advertisement.

Answers are now received at this Office, by special arrangement, to advertisements appearing in THE LANCET.

The Manager cannot hold himself responsible for the return of testimonials, &c., sent to the Office in reply to Advertisements; copies only should be forwarded.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Office, 423, Strand, London, to whom all letters relating to Advertisements or Subscriptions should be addressed.

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France—J. ASTIER, 31, Rue Bapts, Asnières, Paris.

causes; the female deaths from alcohol represent 16·3 per cent. of the female deaths from all causes. The male alcoholics represent 30·5 of the total male admissions, the female alcoholics represent 14·5 of the total female admissions. Alcohol is thus *directly* responsible for 23·16 per cent. of the total admissions—i.e., 471 cases were admitted either suffering from delirium tremens or from alcoholic dementia or from mental confusion or delusional insanity occurring in a patient showing unmistakeable signs of prolonged alcoholism. In what proportion alcohol is indirectly responsible for other classes of mental breakdown we have no exact data. Constant nipping or beer-swilling insufficient in amount to cause a condition even approaching intoxication and which would never give rise to delirium tremens *may*, and I believe *does*, by continuous action so impair the brain tissue as to make it less resistant and less capable of maintaining a healthy intellectual equilibrium.

The symptoms of delirium tremens are so well known and so easily recognisable that I do not propose to add to the many descriptions of the disease. The early symptoms in the less severe cases are not so easily diagnosed and may consist of merely a slight tremor of the hands, the tongue, and the lips, and a tendency to talk a little at random; especially is this the case when delirium tremens supervenes in a case admitted for an injury. The first thing noticed is often a confidential and mysterious manner assumed by the patient, unwarranted by circumstances. The subject matter may be the delinquencies of some person of whom you have never heard, or there may be a slight restlessness of the hands or a continual peeping about the ward. When these signs are associated with sleeplessness they should at once be recognised as heralds of an approaching storm. The statement that a cat has been sitting on the patient's bed or that a strange dog has been gambolling about the ward naturally invites the attention and suggests investigation for the discovery of other symptoms. The occurrence of epileptiform convulsions in delirium tremens is not infrequent and is of grave omen. Sudden cardiac failure sometimes occurs. A considerable difference of opinion exists as to whether the sudden cessation of drinking will induce an attack of delirium tremens. I certainly believe that it is so produced, otherwise it is difficult to account for the onset of the condition three or four days after admission in persons in the workhouse who were apparently quite healthy and normal upon entrance. I have seen it develop repeatedly in the infirmary in patients admitted for some minor ailment. They certainly had no suggestion of the condition when they came in and it is equally certain that they had no drink since admission. What else except cessation of the stimulant is to account for the onset of the disease?

The influence of sex is shown in the larger proportion of males—335 men as against 136 women:—

Males.		*Females.*	
Sent to asylums ...	13 = 3·9%	Sent to asylums ...	5 = 3·6%
Recovered	280 = 83·6%	Recovered	123 = 90·4%
Died	42 = 12·5%	Died	8 = 5·9%

The greater recovery-rate and the smaller death-rate amongst females are what would be anticipated from the known greater addiction of the male to drink. He dies from the effect of alcohol upon his heart and so his ultimate mental condition is unknown. Generally a woman has delirium tremens in a more lady-like way than a man. Her hallucinations are not so grotesque and fearsome as those of the male and are mainly confined to mice and smaller vermin, while her struggles are not so strenuous nor are her imaginary labours so intense as those of the male. This is due to the influence of previous occupation. The carman drives ghostly horses, the barman draws imaginary beer and counts elusive coins all with tremendous difficulty and with great stress. The woman's concern is mainly with the bedclothes, which suggest to her some cleansing or sewing operation, still, however, causing much anxiety and perturbation.

Some cases of mental confusion appear to be caused entirely by drink. The patients are usually found wandering by the police and have no hallucinations or feeling of terror but are simply lost and unable to give any account of themselves. They recover with a good purge and a sleep. Many of the women are secret drinkers. Several of them have been cooks from houses in the better class districts. A considerable proportion have been, however, known frequenters of public-houses, which the lowest class of women frequent, perhaps, equally with men. 403 out of 471 alcoholics (85·5 per cent.) recovered and they amount to 39·5 per cent. of the total 1020 recoveries from all causes.

The treatment of delirium tremens involves the greatest care and attention on the part of the medical man and necessitates the employment of trained attendants upon whom absolute reliance can be placed. My routine plan is after a warm bath to give five grains of calomel and one ounce of house mixture, or as an alternative two or three drops of croton oil in hot milk, and to put the patient to bed at once under the charge of a separate attendant. As a matter of course these patients will not want to stay in bed, the horses have to be attended to, or a customer in the front bar wants to be served and they *must go at once*. Often they can be humoured and coaxed; sometimes they have to be restrained. Now restraint must be at once effective and judicious, and unless kept within well-defined bounds has to be reported to the Commissioners in Lunacy. A patient may not be tied to a bed or any other object, nor may his limbs be tied together or to his body without the reasons for, and the duration of, the restraint being registered and reported, but he may be very completely tucked in by bedclothes and he may have a stout ticking coverlet lashed over the bedclothes to the bed, which will suffice to modify the movements of the majority. Some, however, either burst their coverings or engage in so exhausting a struggle with their imaginary duties that further physical restraint is inadvisable and these patients must be placed in the padded room warmly dressed and with a mattress and pillow to lie upon. If a patient should strip himself or tear off his clothes a canvas suit of trousers and jacket buckling behind may be put on over his clothes. He, of course, will not lie down, but it does him less harm to walk about than to be engaged in a constant struggle. He must be fed at frequent intervals, say every three hours, with warm egg and milk and beef-tea, taking four pints of milk and four eggs in the 24 hours. If he refuses nourishment and will not listen to the suggestion that the cup contains some of his favourite beverage, then he must be fed nasally. To effect this the largest-sized œsophageal tube which will pass into the nose should be used. No. 18 is a usual size, it enters the œsophagus much more easily and does not tend to get into the larynx nor can the patient cough it out into the mouth as often happens to the small-sized catheters generally used. The goal aimed at in the treatment of delirium tremens is the production of sleep, because we know that nine out of ten cases recover if we can achieve that result. In mild cases a hot bath and a good drink of hot milk or beef-tea will be sufficient, but in most instances some drug will be requisite, and I trust that nobody will be sufficiently credulous as to believe the story, still copied into works on therapeutics, of the Jersey practitioner who gave a patient suffering from delirium tremens an ounce of tincture of digitalis by mistake and was amazed to find him cured instead of dead. There are two explanations: either he made a mistake in thinking he had given him tincture of digitalis, or if he really gave it it was inert. A medical man told me 20 years ago that he once tried it; the result was what we might anticipate and it did not encourage a repetition on another patient. Opium and morphine are long in acting and appear to have a cumulative effect in that they act suddenly, and it is difficult to gauge the probable effect which a given dose will produce. Repeated small doses produce no effect at all, then a slightly increased dose produces effects out of all proportion to the increase. To the coal-tar preparations, sulphonal, trional, veronal, I have given an extended trial and have discontinued their use. Their action is too slow and too uncertain, the personal element is difficult to estimate, and the cardiac attacks which occasionally occur during their administration are disconcerting to the friends and dangerous to the patient, while the peculiar and varied skin hues and rashes following their use are not encouraging. I have never seen either sleep or calm produced by the hypodermic injection of any preparation of hyoscine, but, on the contrary, I have often seen intense cardiac depression follow its use. Paraldehyde, except as an emetic, is inert up to doses of half an ounce. In fact, the only combination upon which one can rely is a mixture of 30 grains of potassium bromide and 20 grains of chloral hydrate with a little tincture of lavender and water to an ounce. This may be given every four, three, or two hours for two, three, or four doses according to the severity of the case. Alcohol I do not give, but ten grains of ammonium carbonate in some hot milk, or four minims of solution of

This gives a recovery rate of 50·13 per cent., an asylum rate of 39·54 per cent., and a death-rate of 10·3 per cent.

The above figures show conclusively that, *relatively*, more females than males go to asylums, that more males recover than females, and that more males die than females.

During the decade chosen we have had the periods of stress and excitement caused by the Boer war and we have experienced the distress and poverty which invariably follow in the wake of a struggle involving great sacrifice and sub- sequent retrenchment and monetary stringency. The figures with which we are dealing are, however, too few in numbers and too easily influenced by accidental disturbances to reflect accurately any general and widespread movements, and in addition we have to reckon with the fact that Lewisham has by its rapid development changed during the past few years from a semi-rural locality to a district crowded with small villa residences.

Alcohol.—Alcohol, in accordance with previous experience, is directly responsible for a large number of admissions—471 cases, representing 23·16 per cent. of the admissions from all causes. Of these 403, or 85·5 per cent., recovered; 18, or 3·8 per cent., were sent to asylums; and 50, or 10·6 per cent., died. Thus alcohol furnishes 39·5 per cent. of the total recoveries; 2·24 per cent. of the cases sent to asylums; and 23·9 per cent. of the total number of deaths.

The influence of sex is striking and interesting. The male alcoholics numbered 335, or 71·1 per cent. of the alcoholic cases, while the female alcoholics numbered 136, or 28·9 per cent. Of the 18 cases sent to asylums 13 were males and five were females, the males representing 3·7 per cent. of the total number of males sent to asylums and the females representing only 1·1 per cent. of the number of females sent to asylums for all causes. Of the 403 recoveries 280, or 69·5 per cent., were males and 123, or 30·5 per cent., were females. The male alcoholic recoveries represent 47·7 per cent. of the male recoveries from all causes, while the female alcoholic recoveries account for 28·4 per cent. of the female recoveries from all causes. Of the 50 deaths from alcohol 42 or 84 per cent. were of males and eight or 16 per cent. were of females.

alcohol represent 26·2 per cent. of tl

Mania.—Of 149 cases of mania 49, or 32·9 per cent., were those of men, while 100, or 67·1 per cent., were those of women. 123, or 82·5 per cent. of these cases, were sent to asylums; 21, or 14·1 per cent., recovered; and five cases, or 3·3 per cent., died. Of the 49 males, 36, or 73·4 per cent., were sent to asylums; 11, or 22·4 per cent., recovered; and two, or 4·1 per cent., died. Of the 100 females, 87 per cent. were sent to asylums; 10 per cent. recovered; and 3 per cent. died.

The line of treatment must be, first, attention to the bowels and feeding and sleep. It is for these patients that a padded room is almost essential. Their actions are so sudden and their violence so spontaneous that they can neither be trusted nor left unattended. Exaltation is rarely confined to one emotion. An augmentation of religious feeling is always associated with a desire to sing and also with a marked increase of eroticism manifested by a desire to strip and to indulge in self-abuse.

Stuporous conditions.—These conditions account for 141 cases, of which 61, or 43·26 per cent., were those of men, and 80, or 56·7 per cent., those of women. 56, or 39·7 per cent., of the total were sent to asylums; 82, or 58·1 per cent., recovered; and three, or 2·1 per cent., died, one of these being a female case of myxœdema. Of the 61 males, 27, or 44·2 per cent., were sent to asylums; 33, or 54·1 per cent., recovered; and one, or 1·6 per cent., died. Of the 80 females 29, or 36·25 per cent., were sent to asylums; 49, or 61·25 per cent., recovered; and two, or 2·5 per cent., died. This class includes all those cases characterised by loss of memory and by an inability adequately to appreciate environment and which range from a slight mental confusion to a blotting out of all previous experience, together with a marked limitation of the power of receiving fresh impressions. The mother who, overworked by domestic duties, over-taxed by a too frequently recurring maternity, "finds the children too much for her" and feels muddled. The person who wanders away from home and is found some days after by the police, footsore, weary, and very dirty, unable to give a name or any connected history represents the other end of the sequence. These cases resemble the delusional and melancholic classes very much, the delusional element being absent and the mental confusion being much more pronounced. I believe it to be due to a toxic condition and for causation and treatment I have nothing to add to the suggestions made for delusional insanity and *melancholia*.

General paralysis of the insane.—This class was represented by 83 cases, 79, or 95·2 per cent., being men and four, or 4·8 per cent., being women. 72, or 86·7 per cent., were transferred to asylums; five, or 6 per cent., recovered their mental equilibrium sufficiently to be handed over to their friends; and six, or 7·2 per cent., died. Of the 79 males, 69, or 87·3 per cent., were asylum cases; four, or 5 per cent., improved; and six, or 7·6 per cent., died. Of the four women three were sent to asylums and one improved.

Senile dementia.—This condition furnishes 190 cases, of whom 119, or 62·6 per cent., were males, and 71, or 37·4 per cent., were females. 28, or 14·7 per cent., of these were sent to asylums; 68, or 35·8 per cent., recovered sufficiently to warrent their discharge; and 93, or 49 per cent., died. Of the 119 males, 14, or 11·7 per cent., were sent to asylums; 32, or 26·8 per cent., were relieved and restored to their friends; and 73, or 61·4 per cent., died. Of the 71 females, 15, or 21·2 per cent., were sent to asylums; 36, or 50·7 per cent., were relieved and restored to their friends; and 20, or 28 per cent., died. Senile dementia varies markedly in degree and ranges from a slight forgetfulness for recent events to a condition indistinguishable in its intensity from acute mania. In its common form the patient may be to all appearance perfectly rational during the day, but as evening approaches restlessness becomes marked, the sense of present environment is lost, and the patient is translated to some earlier epoch of life. If a woman she is with her children. Sometimes they are babies and she is nursing them or is fearful that they are in danger of being burnt; sometimes they are grown up and she is directing a daughter to perform some domestic action. In old men the thoughts wander back to work, although occasionally from phrases and gestures employed, a tavern carousal would appear to be the concern on hand. I have never observed the slightest sexual suggestion either in men or women.

There is a growing feeling that cases of senile dementia should not be classed as lunatics. The county asylums object to their presence because they are incurable, they occupy valuable and needful space, and they depress the recovery ratio in a marked manner. The Metropolitan Asylums Board asylums superintendents also object to them—an objection which appears somewhat unreasonable as the Metropolitan Asylums Board asylums were built especially to relieve workhouses from the presence of these cases. Old people who cannot find their way about a ward, who are unable to recognise their own beds, who prowl about the place in a semi-nude condition, who try to get into bed with other inmates and who resent their exclusion, who sing and chatter and call upon imaginary persons all night, who would, if not prevented, light fires upon the floor, are not sufficiently docile to be retained in ordinary workhouse dormitories, while their presence in an infirmary ward would be intolerable. If the asylums will not have them it must mean the erection of separate incurable mental blocks. From the relatives' point of view it is regrettable that an affection which is really due to senile decay rather than to disease should inflict the stigma of insanity upon the family stock. The high male death-rate is accounted for by the fact that the acutely maniacal cases, and which are nearly all fatal, occur much more frequently in men. Again, fewer women are admitted because they are much more easily managed at home and when treatment has quieted them down the friends receive a mother or grandmother back again much more readily than they will an old man. A woman is much more docile and domesticated, whilst a restless old man is an intolerable nuisance in a small house.

For treatment the milder cases who turn night into day and *vice versâ* should be kept awake at day and put to some light work; there is then more chance of them sleeping at night. In these, as in other cases, I believe that a full dose of bromide of potash and chloral hydrate, 30 grains of the former and from 20 or 25 of the latter, is the best and safest hypnotic. Small doses by cutting off the control of the higher centres and increasing the automatism of the patient's actions aggravate the restlessness and garrulity.

Epilepsy with mental derangement.—These conditions supplied 112 cases, 81, or 72·3 per cent., being those of males, and 31, or 27·7 per cent., those of females. In 22 males and in ten females the mental symptoms, which consisted in violence and hebetude after a fit, were sufficiently marked to necessitate their detention in an asylum. In 53 males and in 21 females the condition was sufficiently alleviated to permit their return home. Six males died in the condition known as status epilepticus. The treatment of epilepsy is exceedingly unsatisfactory; except in acute conditions I rarely administer drugs.

Idiocy.—Idiocy accounts for 75 admissions, 50, or 66·6 per cent., of the patients being males, and 25, or 33·3 per cent., being females. 18 males and five females were transferred to idiot asylums, the friends of 30 males and 19 females were induced to take them again under their care, and two males and one female died from intercurrent affections.

Temper.—In temper as a cause of admission we have instances of wild ungovernable outbursts which were alarming and of maniacal intensity in some cases. The sexes are nearly evenly balanced—ten males and nine females, all of whom recovered. The discipline of a mental ward, with the faint suggestion of a lunatic asylum in the background, is a splendid corrective.

Malingering.—There were seven cases of malingering, all the subjects being males. Some were old asylum patients who evidently desired to return to a haven of comparative rest from the strife of competition. One was a simulation of the popular conception of hydrophobia, enacted by a youthful mime to impress the female employees of a drapery establishment. The interrupted current terminated the performance.

Cardiac mania.—This condition, in which the mental affection was obviously the result of valvular disease, was responsible for seven admissions, three males and four females. One patient, in whom a noisy dementia supervened, was sent to the asylum; four patients recovered and two died.

Delirium.—There were 19 cases of delirium, ten males and nine females. In one case of acute delirious mania, that of a male, the patient was sent to the asylum. The other patients were the subjects of symptomatic delirium, of enteric fever, pneumonia, gangrene, epitheliomata, &c. Six patients recovered and three died.

Hysteria.—Of 48 cases of hysteria three of the patients strychnine hypodermically are excellent cardiac stimulants. By keeping a close watch upon your patient you will notice the onset of drowsiness and can then get him into bed where he will sleep soundly for eight or ten hours and be drowsy and perhaps muttering for another 12 hours. At the end of that time his mental condition should be practically cured, but in some cases after a brief period of semi-consciousness he drifts into a condition approaching coma characterised by low muttering delirium, dry tongue, collection of sordes upon the teeth and lips, and incontinence of urine and fæces, he lies flat on his back and takes no notice of, anything, he asks for nothing, and if let alone, beyond moving his head from side to side and some non-purposive movements of the arms, he will remain in the supine position. His heart becomes rapid from peripheral neuritis of the vagus and if he does not succumb to hypostatic pneumonia he may develop peripheral neuritis of the legs or paralysis of the intercostals or diaphragm from the same reason. The treatment for the condition is scrupulous cleanliness, attention to the back and heels to avoid bed-sores, and catheterisation of the bladder; turning the patient from one side to the other at intervals of an hour and fixing him in the desired position by pillows. This will enable the upper lung to act with freedom and it also prevents the accumulation of blood at the bases of the lungs. The most careful attention must be given to the toilet of the mouth, otherwise inflammation and swelling and possibly abscess of the parotids will ensue from a spreading septic infection of the duct. Nasal feeding is usually requisite although sometimes fluid may be carefully administered through a feeding cup. Large doses of ammonium carbonate internally and three or four minims of solution of strychnine hypodermically four-hourly form the most successful line of treatment.

There is a condition of alcoholic dementia into which a drinker may lapse after any acute illness without any suggestion of delirium tremens. He hovers between semi-consciousness and semi-coma. He recovers when roused and recognises his friends when sufficiently pressed. He will take food so long as too much trouble in mastication is not required. He can get out of bed and can walk, or rather stagger, round the room. He will talk sensibly for a minute or so and then relapse into incoherency. He is usually jaundiced, with a foul tongue and with a slightly increased range of temperature. His dangers are hypostatic pneumonia and peripheral neuritis, otherwise he may recover in two or three months.

After an attack of delirium tremens the bodily health may be entirely regained and yet the mental condition may be one of varying degrees of dementia which may range from a mere loss of memory for recent events to a total inability to appreciate environment. These are the cases which, classed as alcoholics, we transfer to the asylums.

Delusional insanity.—The next group is that of delusional insanity and here the dividing line between this group and melancholia is not very definite. Many delusional patients are depressed and most melancholics have delusions. I have included in the delusion class all those where the delusion appears to be primary and where the depression (if existing) seems to be the result of the delusion, and amongst the melancholics I have classed those whose delusions have apparently arisen from antecedent mental misery. Out of 407 admissions 283, or 69·5 per cent., were sent to asylums; 118, or 29 per cent., recovered; and six died.

Males (178 admissions).		*Females (229 admissions).*	
Sent to asylums ...	110 = 61·8%	Sent to asylums ...	173 = 75·5%
Recovered	63 = 35·4%	Recovered	55 = 24·0%
Died	5 = 2·8%	Died	1 = 0·5%

Considering the cases as a whole, it seems strange that 29 per cent. of cases admitted for so grave a condition as delusional insanity should recover in the short period of, say, 17 days. I have no doubt that in some of these recoveries the exciting cause of the breakdown has been alcohol, although there has been no suggestion of tremor or other indication of delirium tremens. Pulmonary tuberculosis is a frequent cause of delusional insanity, and here an improvement of the general health is often associated with a loss of the delusion. Cardiac valvular disease is another cause. Uterine myomata and other abnormal womb conditions are sometimes associated with delusions and their removal or alleviation is followed by mental equilibrium. I recall one case where I removed an ovarian cyst in a woman whose delusions of persecution disappeared on her restoration to health.

Another point which would repay elucidation is the after-history of these delusional cases. How many of them turn out to be early cases of general paralysis where the mental symptoms have preceded the physical. We rarely see a case of general paralysis in a woman in an infirmary and yet they are not uncommon in asylums. Many of these cases are suicidal and necessarily require constant supervision. Some may be homicidal but I can recall only one definitely homicidal case in the whole of my experience, although many had distinct ideas of persecution by definite persons. A sudden accession of resentment and a favourable opportunity might furnish the exciting cause for the commission of a deed of violence and where the idea of killing is entertained it is generally associated with a feeling of affection for the intended victim, who is usually a wife or child, most of the would-be executioners being alcoholics in a state of delusional depression. Again, most of the male suicides are depressed alcoholics. The majority of suicides and attempts at self-destruction which come under my notice occur in young women and the chief point of interest is the relatively unimportant motive which leads to the act. "My mistress was cross with me," is a very frequent reason alleged. The favourite poison at present is the disinfectant solution supplied for the asking by the borough council, which, whatever its bactericidal properties may be, is not followed by any great fatality when taken as a beverage. A few days ago a woman took half a pint of it "because her teeth ached," which seems a trivial reason for wishing to terminate her existence. Spirits of salt (commercial hydrochloric acid) is easily obtained and evidently has a reputation as an agent for self-destruction; its effects are awful and the lingering sufferings of its victims are pitiable in the extreme. Both men and women occasionally attempt to drown themselves in the Ravensbourne; they always think better of it, its smell is so pungent that, although anxious to face death, they are not prepared to meet it in so horrible a form. Cut-throats are mostly males; occasionally a woman attempts it, but it is a very half-hearted performance. I presume that topographical anatomy is not yet a compulsory subject at the Council schools, as the carotids continue to escape. It is sometimes strange that they are not injured. I recall a case where the trachea and œsophagus were completely severed and the vertebral column deeply nicked by a razor without any important artery being cut. After careful suturing of the divided structures he recovered. Gun-shot attempts are confined to males. As an example of a determined suicide may be mentioned a man who threw himself from a window and broke his neck. The fracture could easily be felt both behind and in the pharynx. The spinal cord was not injured. By encasing his shoulders, neck, and head in plaster-of-Paris we obtained very good union of the fracture, and as his delusions persisted he was, after some weeks, transferred to one of the county asylums. After a few months he was discharged and within a few days of obtaining his freedom he threw himself under a brick-cart, this time with success.

Melancholia.—This condition is responsible for 233 admissions, of whom 141, or 60·5 per cent., were sent to asylums; 91, or 39·5 per cent., recovered; and one died (a female committed suicide). Of the 80 males, 41, or 51·25 per cent., were sent to asylums; and 39, or 48·75 per cent., recovered. Of the 153 women, 100, or 65·3 per cent., were sent to asylums, and 52, or 33·3 per cent., recovered. Comparing the sexes, we note that 153, or 65·6 per cent., were women, and 80, or 34·3 per cent., were men. The asylum rate of women is greater than men—65·3 per cent., as against 51·25 per cent. The recovery rate is less—33·3 per cent. of women, as against 48·75 per cent. of men.

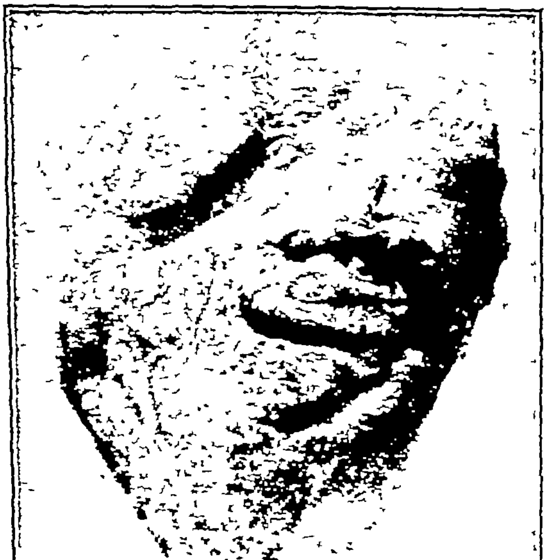
In both delusional insanity and melancholia the line of treatment is the same. Search for some physical cause, examine every organ carefully—the lungs, the heart, and the uterus. The digestive tract will inevitably be out of order. Constipation is always present. Pyorrhœa alveolaris, with its attendant foul discharge into the mouth, swallowed and absorbed, is a frequent accompaniment. Some of these cases of depression have mouths which are charnel houses of decayed teeth. Start with a brisk purge, five grains of calomel or five grains of blue pill, followed by a saline draught, attend to any faulty bodily condition, give the patients sleep by means of a full dose of chloral, keep them in bed, and if they are of poor nutrition, as is usually the case, feed them up with abundance of milk and eggs.

was turned downwards. In freeing the third cartilage the pleura was wounded. The rent, about half an inch in length, was at once clipped with artery forceps and closed by two sutures. A rent in the pericardium about two and a half inches in length was now exposed through which blood was slowly escaping. The pericardium was full of blood-clot which was gently sponged away, a piece of bone one inch by half an inch was removed, and a small spicule of bone was felt imbedded in the heart and extracted. On further examination a wound was felt in the right ventricle and on following this along another piece of bone was felt. This was seized with forceps and removed and its removal was followed immediately by a terrific gush of dark blood. I at once plugged the wound in the heart by plunging my fingers in and found that the insertion of three fingers practically stopped the hæmorrhage; I also found that my fingers were within the cavity of the heart, the index being separated from the middle and ring fingers by a band of tissue, which at the time I took to be the anterior flap of the tricuspid valve. Three sutures were inserted, withdrawing a finger as each was passed and by them the wound was roughly drawn together, and then ten sutures were passed through the muscular coats, using the first three, which were left long, to steady the heart and bring the wound into view. A second row of ten Lembert sutures were passed through the pericardial serous coat closing in the first row. The wound was now quite closed and no bleeding was going on. After the first flow of blood transfusion into the saphena vein of the right leg was commenced but was stopped as the immediate increase of blood pressure increased the hæmorrhage. The transfusion was continued when the first row had been tied. The contractions of the heart became very lively as each suture was inserted and but for this somewhat violent stimulus it appeared several times that pulsation would have ceased. The pericardium was cleansed with gauze and partly closed with a row of sutures, the fragment of sternum was replaced, and the wound was closed except at its upper and lower angles. The fragments of the third and fourth costal cartilages, having their sternal ends also detached, were not replaced. The wound was irrigated freely with sterilised water and dressed with double cyanide gauze.

During the operation a second hypodermic injection of six minims of liquor strychninæ were given and at 5 P.M., when the patient was in bed, a further injection of five minims was given; also an enema of saline solution (half a pint) and brandy (half an ounce). His pulse was 116, regular, and of fair force, but small volume. He recovered consciousness by 5.30 P.M. and complained of thirst and was given sips of lime juice and water. At 7 P.M. he was restless and sick. The dressing had come through but was not disturbed. The temperature was 97·6° F. The sickness continued at intervals through the night. On the 22nd, at 5 A.M., half an ounce of brandy and the white of an egg in half a pint of saline solution were given as an enema and at 7 A.M. three minims of liquor strychninæ. At 8 A.M. the temperature was 100°, the pulse was 116, and the respirations were 30. At 9 A.M. the enema was repeated; the patient was rather drowsy. The injection was repeated at 12.30 P.M. and 3.30 P.M. The patient complained of no pain, but a feeling of weight in the chest and slept a few minutes at a time all through the day. The pulse-rate kept at about from 120 to 130, but the respiration rate rose at 2.30 P.M. to 72, falling by 5 P.M. to 61. The wound was dressed at 7 P.M. There was no hæmorrhage but free serous discharge. He was given an enema of half an ounce of brandy and half a tin of Brand's essence was given in five ounces of saline solution. He slept most of the night quietly, but on waking occasionally would have an attack of restlessness with difficulty in breathing. The enemata were repeated every four hours. At midnight the pulse was 120 and the respirations were 48. He took sips of water or milk-and-water continually when awake. A few râles were heard over the base of the left lung in the axillary region but no signs of pneumothorax were present. On the 23rd the wound was dressed at 1.30 A.M. There was a free serous discharge which was slightly turbid. The respirations were 45. The pulse was 118 and more thready than ever before; it improved after five minims of liquor strychninæ were given hypodermically. During the night he had six bouts of restlessness, all following the same course, the pulse first becoming thready and more frequent; an attack of dyspnœa followed with some pain in the chest, the patient becoming restless for a time. During the day these attacks were slighter and less frequent and he slept most of the time. He was very thirsty and took about three ounces of milk-and-water every hour. On the 24th at 12.30 A.M. the pulse was 144 and irregular. The patient was sleeping quietly. He had a fairly comfortable day. There was free discharge from the wound, which was dressed twice. The fluid draining from the wound was serous and evidently pericardial; the quantity soaking into the dressing was very considerable. At midday there was a very free escape of fluid, and after this his breathing and pulse improved very much and he had no severe dyspnœic attacks during the rest of the day. On the 25th he was still very thirsty and drank milk and albumin water freely. He was sleeping well and quietly, but his breathing was noisy when awake; a few râles were still present. At 3 P.M. he had a slight rigor; the pulse was very thin and 135 per minute. He was given a hypodermic injection of three minims of strychninæ and six minims of tincture of digitalis, and at 4 P.M. the pulse was much improved—126 per minute. On the 26th the patient had passed a very fair night. He was rather faint at 6 A.M. but improved after five minims of liquor strychninæ had been administered hypodermically. The wound was dressed at 8 A.M. and 5 P.M. The bowels were freely opened after an enema of soap and water and two drachms of turpentine. He had a comfortable day but perspired freely at times. No râles were to be heard now and breathing was quite easy.

The patient's condition improved a little each day till June 29th. The wound was dressed every eight hours after the 26th as the lacerated skin and subcutaneous tissue at the site of the original injury appeared likely to slough. On the 28th some of the stitches were removed as they were cutting through the skin. The wound was irrigated at first with biniodide solution 1 in 4000 and later with sterilised water and lightly packed with gauze. On the 29th the wound was clean and more healthy except at the edges of the fissure in the sternum where there were a good many shreds of necrosing aponeurotic tissues. On the 30th he had several attacks of faintness and at 11 P.M. there was a little blood on the dressing but no hæmorrhage was apparent on

FIG. 2.



Appearance of heart after removal. The stitches have been removed and the wound opened up. The left ventricle has been cut away up to the interventricular septum.

were males and 45 were females. They all recovered. All were the subjects of emotional storms of prolonged duration.

Mental derangement associated with gross brain lesions.—There were 38 cases under this heading, 28 of the patients being males and ten being females. Some were cases of cerebral hæmorrhage, some of brain tumours, while others were those of syphilitic endarteritis. Two of the patients were sent to asylums, 15 recovered, and 21 died.

Puerperal mania.—This condition was responsible for 25 cases. 21 patients were sent to asylums, three recovered, and one died.

Amongst unclassified cases were the following: one case of a male who was the subject of pernicious anæmia with delusions and who died; another of a male who suffered from locomotor ataxy with delusions and who recovered his mental balance; a third of a male who had contracted the cocaine habit and had suffered from delusions and who recovered; three cataleptic cases among females (one was sent to the asylum and the other two recovered); and two cases of domestic infelicity in which the wife succeeded in securing the temporary incarceration of a husband with an ill-regulated temper, both being released after examination.

My object in choosing this subject for my presidential address is to bring to your notice the curability and the temporary nature of the large proportion of mental cases. 50·3 of our cases have recovered; 39·54 only have gone to asylums. As honorary secretary of the lunacy committee of the Metropolitan Workhouse and Infirmary Medical Officers Conference I have collected the figures for London for the last four years.

Years.	Cases.	Sent to asylums.	Cured.
1902	8076	3920	3560
1903	8004	3782	3443
1904	7654	3716	3165
1905	7322	3583	2877

These figures show that so far from lunacy having increased in London it has in four years steadily decreased, being 754 less in 1905 than in 1902, the numbers sent to the asylum from the workhouses and infirmaries being also 337 less. I strongly urge that the Lewisham system should be everywhere adopted and that no case should be sent directly to an asylum, but that all should go through the sifting process of the infirmary half-way house. For cases who are not paupers a difficulty at once arises, for directly an institution be established to deal solely with mental cases, whether in their incipient or later stages, it immediately becomes in the eyes of the public a lunatic asylum and the stigma of lunacy adheres to all who accept its help. The solution is in attaching a mental block to each general hospital, an arrangement beneficial to both the public and the profession. I would discourage the practice which still obtains in a few districts of certification by the family attendant of the justice. I know of one case where a consulting oculist was given a turn at a pauper case in a London workhouse. A strange practitioner, seeing the patient for a few minutes, then and there determining his destination, to the exclusion of the medical officer who has all the available knowledge concerning the individual and all the responsibility of his care and treatment, reduces the working of the Act to a mere farce.

May I, in conclusion, express the opinion that the result we have achieved in Lewisham is one of which we may justly feel proud. It has required, and it has received, the loyal coöperation of all authorities—of the Blackheath bench of magistrates, of the Lewisham board of guardians, and the medical officers and the relieving officers. The knowledge that 1020 persons have been spared from being branded as lunatics cannot be other than a source of gratification to all concerned.

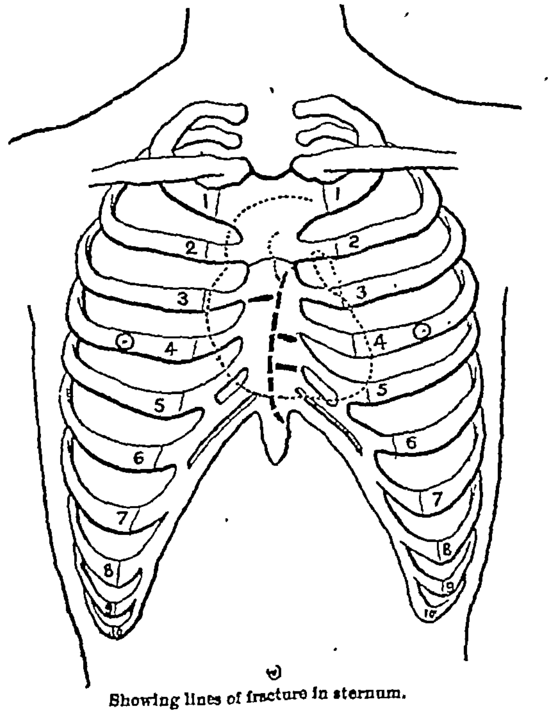
PHARMACEUTICAL SOCIETY OF GREAT BRITAIN.—The sixty-fifth session of the School of Pharmacy of this society will commence on Monday, Oct. 1st, when the President will present the Pereira medal, and the inaugural sessional address will be delivered by Sir George Watt, M.B., C.M., C.I.E.

SUTURE OF PERFORATING WOUND OF THE HEART; DEATH ON THE ELEVENTH DAY.

BY FREDERICK T. TRAVERS, B.S. LOND., F.R.C.S. EDIN.,
HONORARY SURGEON TO THE WEST KENT GENERAL HOSPITAL.

AT 11.30 A.M. on June 21st the patient, an active lad, aged 19 years, after climbing over the surrounding fence, some six feet high, scrambled on to the upper stone of the cromlech known as Kit's Coty House. This stone is about eight feet from the ground and the railings are about three feet distant from it. He attempted to leave by stepping on one of the longer spikes of the fence from the stone. In doing so his foot slipped and he fell forward and was impaled on the spike. He managed to lift himself free and fell inside the fence. Nearly an hour elapsed before medical aid could be obtained or the assistance necessary to lift him on a hurdle over the fence. He was brought to the hospital by Dr. T. A. Palm of Aylesford at 2.45 P.M. I saw the patient immediately after his arrival at the hospital; his clothing was saturated with blood, he was just conscious, blanched, with small frequent pulse and sighing respiration. There was a transverse wound about two inches in length over the lower end of the sternum, through which a vertical fissure in the bone could be seen. There was little bleeding. (Fig. 1.)

FIG. 1.



Showing lines of fracture in sternum.

As the account given rendered injury of the structures within the chest probable I thought it advisable to anæsthetise the patient and to explore the wound. Six minims of liquor strychninæ were given subcutaneously, and chloroform was administered. The fragments of the sternum were separated and the finger introduced. A loose piece of bone and beyond it the surface of the heart were felt. The wound was therefore extended by a curved incision from its right extremity, running upwards and then to the left. This exposed the lower half of the sternum on the left side; the vertical fissure extended upwards to the second right costal cartilage and there were fractures through the left half between the fourth and fifth and fifth and sixth costal cartilages; the portion between the second and fifth costal cartilages was missing. The third, fourth, and fifth cartilages were divided at their attachment to the ribs and the [illegible] of the sternum non-virulent, and "streptococcus longus" for the long-chained forms, those in which the long chains settle down as a flocculent or granular precipitate, leaving the supernatant broth clear; he showed that the majority of virulent forms belong to this latter type. No doubt there is a certain substratum of convenience and, indeed, of truth in such a division, but as a basis of systematic classification it is inadequate. In one and the same culture chains of the most varying length may be found; the length of the chains may vary according to the chemical composition of the medium in which the coccus grows and may vary on subculture. The length of chain depends upon the degree of cohesion between its constituent cocci, which is not a sufficiently fundamental character. Nevertheless, it is certainly true that some streptococci tend to grow in short chains and some in long, and that short-chained forms are less frequently and intensely pathogenic than long-chained forms. Morphology is, in our opinion, of some degree of value in classification, and should be taken into account, in connexion with other and more fundamental characters. A convenient terminology, as regards length of chain, is as follows: "brevissimus," for the forms occurring chiefly as diplococci; "brevis" for somewhat longer chains (e.g., of from four to eight elements); "medius," for forms showing chains of moderate length (e.g., from eight to 16 elements); "longus" for the long-chained forms; "longissimus" for chains of inordinate length; and "conglomeratus" for those long-chained forms which are contorted into dense balls. The "brevis" types habitually render broth uniformly turbid, while the "longus" and "conglomeratus" types show a clear broth with a stringy or granular deposit; the "medius" type is intermediate in this respect. But no sharp line separates these various types and the terms are merely of convenience in description. Gordon has drawn attention to the occurrence of bacillary forms in certain streptococci when grown on solid culture media, more particularly on blood serum. This character may perhaps prove of some value in classification, but our knowledge of the distribution of these bacillary forms is too incomplete for any final verdict.

Cultural characters upon ordinary laboratory media are of very little value apart from the growth in broth. The minute differences in the modes of growth upon gelatin and agar-agar are too variable for purposes of differentiation. There is, however, one biological feature which we think of definite value—namely, the temperature requirements of the various types. Fischer has introduced the convenient terms "psychrophil" for those bacteria growing best at the ordinary summer air temperature and "mesophil" for those growing best at the temperature of the human body. All the pathogenic streptococci naturally belong to the mesophil group, but while some are capable also of vigorous psychrophil growth others are incapable of growth at 20° C. In judging of this point attention must be paid to the precise temperature of the incubator, for even 2° C. may make all the difference as to whether a given streptococcus does or does not show visible growth on gelatin. A very few streptococci possess the power of liquefying gelatin; we have met with two or three such types to which allusion will be made later. It is doubtful whether more stress should be laid upon such a character than upon the other chemical characters to which we shall have to draw attention.

Staining properties are of no value whatever in differentiating the streptococci. They all stain well with the ordinary basic anilin dyes; none are acid-fast and all the pathogenic forms which we have investigated stain well by Gram's method.

Pathogenic power has naturally received much attention in the attempts to distinguish the different streptococci from one another. It may be looked upon from two points of view—the clinical and the experimental, and these do not invariably coincide in their indications. A streptococcus may be the cause of a septicæmia or of an inflammatory affection in man and yet produce little or no effect when inoculated into an experimental animal. There is, it is true, a broad general correspondence in pathogenic effect upon man and rodents, but it is not universal. In this paper we propose to deal only with those forms of streptococci which we have found clinically to be pathogenic for man. For practical purposes the only test of virulence which can be employed as a routine in examining the streptococci is animal inoculation, the mouse and the rabbit being the most suitable animals. There is a circumstance which deprives this test of a good deal of its value as a means of discriminating between different sorts of streptococci—namely, the great readiness with which virulence is lost and gained by these organisms. After only a week or two on culture media, and in the case of pneumococci after only a day or two, virulence may largely be lost. On the other hand, after one or two passages through a susceptible animal a streptococcus of only feeble virulence may become intensely pathogenic. One and the same strain of streptococcus may at different stages in its career produce now a rapidly fatal septicæmia, now a spreading erysipelas, now a localised suppuration, and now no effect at all. The difficulty may be in part overcome by invariably testing the streptococcus upon an animal immediately upon its isolation from a case of human disease, but it remains true that, useful though it be as a subsidiary test, pathogenesis cannot be employed as a fundamental character for the classification of the streptococci.

The various serum reactions, again, which may be induced against streptococci have so far failed as a means of accurate discrimination between them. Agglutination tests carried out by us with the serum of an animal immunised against a given streptococcus upon a whole series of other streptococci have indeed shown that considerable differences exist; but they are graduated differences, not sufficiently defined to be of more than subsidiary help in classification. Moreover, the technique of streptococcus-agglutination is troublesome and disappointing. No sufficient data are to hand as to the bactericidal and opsonic reactions against streptococci to warrant any conclusion as to their taxonomic value; there is as yet no evidence that any rigidly *specific* limits can be assigned to such reactions even though generic differences may exist.

The difficulties above outlined amply account for the doubt and uncertainty which have hitherto attended the systematic classification of the streptococci. But there remains the possibility of differentiating them by their chemical powers or metabolic reactions—a possibility which has received a remarkable impetus from the recently published work of Dr. Mervyn H. Gordon. Such metabolic differences have already proved of signal service in the differentiation of the members of the bacillus coli group, and it may fairly be argued that ability to utilise this or that foodstuff is a character of quite as fundamental a nature as any that morphology can offer. Some few tests of this nature have been in use for a considerable time—e.g., the power of clotting milk—but Dr. Gordon has been the first to approach the matter in a comprehensive way. His researches are embodied in a paper contributed in the report of the medical officer to the Local Government Board for 1903–04[1] and have since been summarised by him in THE LANCET.[2] His method consists in preparing a sugar-free broth and adding to it 1 per cent. of the test substance, together with some litmus. Ability on the part of the streptococcus to utilise the test substance as food is indicated by vigorous growth with the appearance of a sharp acid reaction. He first tested 33 chemical substances, belonging to the carbohydrates, glucosides, and polyatomic alcohols, upon a series of ten diverse streptococci. Many of these substances were affected uniformly by all ten streptococci, others by none at all, and such substances were rejected as of no differential value. A number of the substances showed, however, marked differences between the different streptococcal strains and from these he selected seven as of special differential value. They included two disaccharides—saccharose and lactose; one trisaccharide—raffinose; a polysaccharide—inulin; two glucosides—salicin and coniferin; and one alcohol—viz., mannite. To these seven tests he added the clotting of milk and the reduction of neutral red, the latter under anaerobic conditions. These nine tests we shall refer to briefly as "Gordon's tests." He proceeded to apply them to a large number of strains of streptococcus, 300 in all, isolated from normal saliva, and he found that he could distinguish no less than 48 chemical varieties. The research was primarily undertaken with the view of ascertaining whether any tests could be found for distinguishing the streptococci of saliva from those of other origin. He tested also a few streptococci from miscellaneous sources, including some from disease-processes in removing the gauze. He became more restless later and wandered a good deal and died at 2.30 A.M. on July 1st.

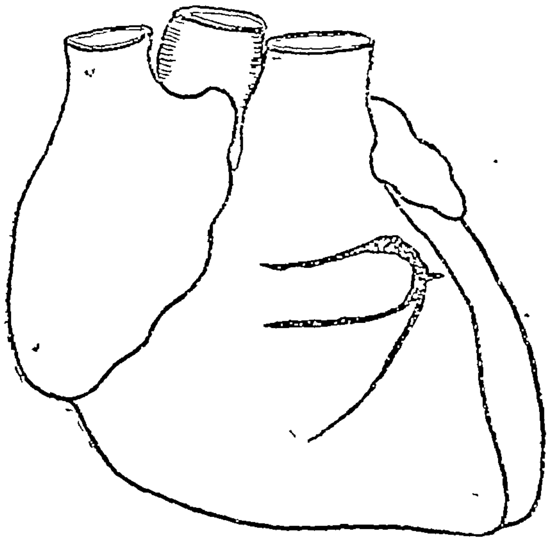
---

[1] Vol. xxxiii., p. 383.

[2] THE LANCET, Nov. 11th, 1905, p. 1400.

At 2.30 P.M. on July 1st an examination was made of the injuries. On opening up the wound there was some recent lymph seen about the divided rib cartilages. There was no blood or clots. The edges of the fractured portions of sternum were necrotic and a further fracture was found running transversely just below the third costal cartilage. The wound in the pleura could not be found. The pericardial wound, two and a half inches in length, was healed with the exception of about a third of an inch in the centre. On opening up the pericardium a clot was seen covering the heart, partially organised and adhering somewhat firmly to it. This was carefully removed and several ounces of dark fluid blood removed from the pericardium; there was no pus in the sac. The wound in the heart was difficult to determine except at its left and upper extremity, the greater part being covered by smooth lymph. The heart was removed with as little handling as possible. (Fig. 2.) There was some recent and firmly adherent lymph on the auricular appendages, chiefly on the right, around the bases of the great vessels, and on the left ventricle, but little on the right ventricle except about the wound. The wound in the heart was well closed except at a point where a small portion of the muscular wall between two parts of the rent showed signs of necrosis. The rent was trifid externally, or rather one long rent with two lateral branches, and was situated altogether in the right ventricle; in the recent state it measured in length two and a quarter inches and extended right up to the inter-ventricular septum. (Fig. 3.)

FIG. 3.



Diagrammatic view of wound. It will be seen that one tear extends to the interventricular septum.

From within the rent appeared to be more irregular and was somewhat)–(-shaped and was only healing at the extremities of the various parts of the rent.

The most noticeable features of the case were the plugging of the wound in the heart by the detached fragment of sternum, which almost entirely stopped the bleeding, and the tolerance shown by the heart to the injury and the handling required at the operation. Pulsation continued regularly while three fingers were held in the wound with their tips within the cavity of the ventricle. The loss of blood was very considerable even then, but the insertion of each suture was observed to act as a very immediate stimulus, and after the insertion of the first row, when the heart's action had become very feeble, the insertion of the second superficial layer of sutures stimulated its action so that it became more regular and forcible. In view of the enormous loss of blood, it was remarkable that there was so little collapse; there was, further, no air-hunger or delirium, though symptoms of cerebral anæmia were, so far as possible, averted by keeping the foot of the bed well raised. The patient recovered consciousness within half an hour of being put to bed and was conscious and rational throughout. The severe injury to the pericardium again, though inducing excessive secretion of pericardial fluid, was accompanied by no symptoms, owing to the free drainage afforded to the sac by the incomplete closure of the wound in it. The cause of death was apparently failure of the heart's action due to the pressure of the clot slowly forming on its anterior surface, which also blocked the pericardial wound and prevented the escape of the blood oozing from the gap in the wound in the heart and not directly due to the slight secondary hæmorrhage.

In conclusion, I wish to say that I am much indebted to Dr. Joseph Ward, house surgeon to the hospital, for his assistance in keeping the notes of the case and for his constant attention to the patient during the 11 days he survived the accident.

Maidstone.

A STUDY OF THE STREPTOCOCCI PATHOGENIC FOR MAN.

BY F. W. ANDREWES, M.D. OXON., F.R.C.P. LOND.,
PATHOLOGIST TO, AND LECTURER ON PATHOLOGY AT, ST BARTHOLOMEW'S HOSPITAL, LONDON,

AND

T. J. HORDER, M.D. LOND., F.R.C.P. LOND.,
MEDICAL REGISTRAR AND DEMONSTRATOR OF MORBID ANATOMY AT ST. BARTHOLOMEW'S HOSPITAL, LONDON; PHYSICIAN TO THE GREAT NORTHERN CENTRAL HOSPITAL, LONDON.

I. INTRODUCTION; DIFFICULTIES IN CLASSIFYING STREPTOCOCCI; GORDON'S METABOLIC TESTS.

ALMOST from the time when streptococci were first shown to be connected with certain morbid conditions in man the problem of the identity or non-identity of the types found in different diseases has been actively discussed. One of the earliest disputes concerned the relationship between Fehleisen's streptococcus of erysipelas and that found by Rosenbach in acute suppurations and named by him streptococcus pyogenes. It is now generally conceded that the two organisms are identical, representing at most two differing phases of virulence. In recent years the innumerable bacteriological investigations which have been carried out upon diseased conditions of every kind have shown that streptococci are associated with a large number of acute and chronic inflammatory affections and blood infections, so that to-day they are justly regarded as amongst the most important of pathogenic bacteria. This advance in our knowledge of their importance and commonness in the production of disease has not, however, been associated with any corresponding advance in our power of discriminating between the different varieties of streptococci concerned. With the introduction of serum-therapy the problem has entered upon a more acute phase. Anti-streptococcal serum occasionally works miracles but is more often without effect of any kind, and it has been suggested that one reason for this may be that there are various species of streptococci at work, and that the miracle comes off when by chance the serum has been produced by immunisation with the same organism as happens to be the cause of the disease. The need for some means of discriminating between the different sorts of streptococci has become greater than ever.

Some pathologists, notably Marmorek, to whom we owe the introduction of anti-streptococcal serum, have stoutly maintained the unity of all the streptococci pathogenic for man. Marmorek based his chief argument upon the facts that bouillon in which one sort of streptococcus has grown is incapable of serving as a culture-medium for any other sort and that all alike show similar hæmolytic power. The general demand for a multivalent serum shows that this view has not gained wide credence amongst the medical profession.

There have hitherto been no satisfactory criteria for judging of the specific characters of the various streptococci occurring in disease. Morphology has proved of little value. The size of the individual cocci varies too little to be of service. More hopeful is the length of the chains formed. In 1891 von Lingelsheim proposed a division into two groups based on this criterion; he suggested the terms "streptococcus brevis" for the short-chained forms rendering broth uniformly turbid and for the most part the post-mortem examination and suffered from a very severe lymphangitis and local suppuration which under prompt treatment with univalent pyogenes serum and free incision ran a favourable course. The pus from his wound yielded a streptococcus which fermented saccharose, lactose, and salicin, but now the saccharose was more vigorously attacked than the lactose. The organism was inoculated into a mouse which succumbed in three days. The streptococcus recovered from the mouse fermented saccharose, lactose, and salicin equally well and proved a typical streptococcus pyogenes. Cases such as this are particularly instructive, showing that even such cardinal reactions as those with the di-saccharides may vary somewhat with varying degrees of virulence. 5. We have the tested reactions under varying external conditions. It seems to us probable that slight differences in the composition of the medium may possibly affect the series of reactions to some little extent. And it is clear that free access of oxygen may have an important influence. In one case a streptococcus which appeared certainly to be an example of streptococcus pyogenes altogether refused to attack lactose under aerobic conditions. But on the exclusion of oxygen lactose was readily fermented—i.e., the need for increased chemical activity under anaerobic conditions seemed to evoke a latent power in the coccus. We have not done sufficient work on this branch of the subject to justify us in making any precise statements as to the influence of anaerobic conditions in modifying Gordon's tests, though it would be a matter well worthy of investigation. The neutral red test has no value at all unless it is carried out anaerobically. We would repeat that, despite the instances to the contrary which we have adduced, the constancy of the reactions for any given strain of streptococcus is on the whole remarkable.

We now pass to the second method by which a judgment may be formed as to the value of Gordon's tests—namely, the correspondence between differences revealed by them and differences of other kinds, such as distribution in nature, pathogenesis, and other biological characters. From the critical point of view this consideration is of even greater moment than the constancy of the reactions. In order to gain the necessary data for forming an opinion on this subject one of us (F. W. A.) undertook the correlation of all the published records obtainable in which streptococci had been tested by Gordon's methods. These are now sufficiently numerous to form a fair basis for criticism. The normal flora of the mouth is represented by Gordon's 300 strains and that of the intestine by Houston's 300. There are also Houston's 172 colonies from milk and more than 200 from air tested by Gordon and published in his report on the Ventilation of the House of Commons (1906). Gordon had examined some 20 pathogenic species and we ourselves have raised that number to over 200. Further, one of us had examined a goodly number of strains from fresh air, sewer air, sewage, milk, and the intestines of herbivorous and carnivorous animals. Altogether there were more than 1200 records of colonies tested. These were entered on suitable printed charts and were then sorted and arranged, so far as might be, into groups and sub-groups. In this way a tentative classification was reached, based upon the metabolic tests, and a broad, general survey of the matter was for the first time possible. At the first glance the results of this laborious correlation were somewhat disheartening. The number of chemical types was bewildering; they were connected by innumerable transitional forms and no clue existed as to which tests were fundamental and which subsidiary, though it was already apparent that some (e.g. the salicin and neutral red tests) were more variable than others. There was, however, one guide which, as in all such taxonomic problems, proved of the greatest help—namely, the numerical frequency of occurrence of any given type. When any arbitrary set of characters is taken as a basis for the classification of a group of natural objects the same phenomena are usually seen—large groups of like objects connected by small groups which differ from them in only one or two particulars. If the numerical frequency of each individual like group is represented by the proportional height of a vertical line and the lines are arranged in series the commoner types stand out boldly above the rarer ones. Only in nature they are plotted out, not in linear series, but in space of two dimensions, as it were, so that the common types stand out as mountain tops above their fellows, each mountain connected by valleys of intermediate types with many of its neighbours. If now the mountains were cut off by a horizontal plane half way up their sides and attention were paid only to the mountain tops, disregarding the valleys, we should have the popular conception of species. The biologist, on the contrary, is more concerned with the intermediate types in the valleys, as illustrating variation and the connexion between allied species. In some groups of plants and animals the mountains are few and high and the valleys very deep. These are the groups which are, so to speak, in a stationary condition—which are not rapidly varying and adapting themselves to new conditions. In other groups, which biologists call "dominant genera," the mountain tops are numerous but not so high and separated by only shallow valleys; these are the groups which are at the moment succeeding in the struggle for existence. We believe that the streptococci are such a group.

Applying the above conception to the streptococci as differentiated by Gordon's test, some sort of law and order is at once introduced into the maze of chemical types, so that they begin to fall into a relatively small number of predominant groups connected by many intermediate forms. A clue is thus afforded as to which are the more and which the less important of the individual tests, though we must confess that no one test has appeared to us infallible. Help is also given by other biological characters, such as length of chain, pathogenesis, hæmolytic power, ability to grow at 20° C., and capacity for resisting desiccation.

III. PROPOSED CLASSIFICATION OF STREPTOCOCCI BASED UPON ALL CHARACTERS AND INCLUDING GORDON'S TESTS.

Taking all these conditions into account the classification of the streptococci became much clearer. We do not propose to enter here in detail into the large question of their general classification but we will state the general conclusions to which the study of the 1200 or so individual colonies has led us. Before doing so we will quote in detail the facts as to one small group of streptococci as an illustration of the chemical variations which may exist within the limits of what is almost certainly a single species, though not a pathogenic one. By far the commonest streptococci in the air of London are forms with chains of medium length, incapable or barely capable of growth at 20° C., forming little or no acid in milk, and quite incapable of fermenting lactose. The positive tests in Gordon's series are saccharose and the two glucosides (salicin and coniferin). Gordon had met with these forms in great abundance in air and one of us (F. W. A.) had also found them the commonest air streptococci in some investigations at Hampstead. They correspond with none of the ordinary human saprophytic streptococci, and the most likely source for them seemed to be the horsedung which forms so large a part of the organic contamination of London air. This view proved correct. On examining fresh horsedung it was found that streptococci were present to the number of 10 million per gramme, far exceeding all other bacteria in numerical abundance, and that these particular air streptococci were the chief sort present, other varieties being present only up to 100,000 per gramme. Further, these forms proved remarkably resistant to desiccation, withstanding drying on garnets for several months. It was thus reasonably certain that this form of streptococcus, which seems entitled to rank as a species, was usually derived from horsedung, or perhaps also from the intestines of other herbivora; it was not found in the intestine of certain carnivora examined (the fox and the stoat). Now the chemical reactions of individual strains, though constant on subculture, varied within certain limits. Most frequently both saccharose and the two glucosides were fermented, but often one or more of the reactions was suppressed. The variations are shown in the following table.

TABLE I.

—	Reactions with Gordon's nine tests.									Frequency in 94 air colonies.	Frequency in 13 horse-dung colonies.
	Milk clot.	Neutral red.	Saccharose.	Lactose.	Raffinose.	Inulin.	Salicin.	Coniferin.	Mannite.		
1	·	·	+	·	·	·	·	·	·	7	0

man. Dr. A. C. Houston applied Gordon's tests (excluding the coniferin test) to 300 streptococci from normal human fæces and found that they fell under 40 different chemical types. His results are contained in a paper in the same volume of the *Local Government Board Reports* as the paper by Gordon just alluded to. He has since published in a report to the London County Council on the Bacteriology of Milk the results of Gordon's tests as applied to 172 strains of streptococci from milk. More than two years ago we began to apply these tests to all streptococci which we could procure from human sources in disease, limiting ourselves to those cases in which there was a reasonable presumption that the streptococcus had a direct or secondary connexion with the disease process. We included the pneumococci in this inquiry, regarding them as members of the streptococcal group. We have now examined considerably over 200 strains of streptococci and pneumococci from human disease-processes, and we consider that we have accumulated sufficient material to warrant us in putting our conclusions before the medical profession. We propose in the first place to offer our criticisms upon Gordon's tests as a whole and to state the value which we have been led to place upon them, and secondly, to tabulate our detailed results as a contribution to the classification of the streptococci pathogenic for man.

II. General Criticism of Gordon's Tests and of the Conception of "Species" amongst Bacteria.

We have already shown how other criteria fail to discriminate sharply between various strains of streptococci. This defect cannot well be urged against the series of metabolic tests which Gordon has devised. The error here is in the contrary direction, and there is no little danger that by a blind insistence on the importance of this or that individual chemical test we may tumble into the pitfall of unwarranted species-mongering. Gordon himself has been careful to abstain from claiming specific value for his different chemical types, but he has not ventured to propose any reasoned scheme of scientific classification based upon his tests. The tests are to a large extent empirical and arbitrary and the groups into which his 300 salivary streptococci fall remind one of the Linnæan system in botany. Had he employed 20 tests instead of nine it is probable that instead of 48 he would have found 100 or more varieties amongst them. It cannot too strongly be insisted that in classifying bacteria attention must be directed to the sum total of biological characters. The difficulty lies in deciding which of the chemical tests are to be regarded as fundamental and which of subsidiary importance. It is clear that they impose upon the organisms subjected to them a set of gymnastic exercises in chemical decomposition which are of varying difficulty. The monosaccharides are too easily broken up to serve as a test at all. The disaccharides, saccharose and lactose, are somewhat more difficult to deal with but offer a relatively easy task, for they are far more frequently attacked than any of the other bodies in Gordon's series; more than 90 per cent. of the pathogenic streptococci can utilise these disaccharides as food. The trisaccharide, raffinose, is a much harder nut to crack and only 21 per cent. of the pathogenic streptococci can attack it with success, while only 3 per cent. of the group can ferment the polysaccharide, inulin. The pneumococci, on the contrary, readily attack raffinose (74 per cent. of those we have investigated) and some 25 per cent. of our pneumococci have been able to attack inulin. The glucosides, salicin and coniferin, are more readily decomposed by streptococci than the higher carbohydrates. No less than 73 per cent. of the pathogenic forms attack salicin, while coniferin is broken up by 28 per cent. The polyatomic alcohol, mannite or mannitol, has been fermented by 21 per cent. of our pathogenic series. As regards the two remaining tests milk has been clotted by 34 per cent. and neutral red reduced by 24 per cent. of our series.

Precisely how the cocci chemically attack the test bodies is at present a matter of conjecture, but we shall probably be near the truth if we assume it to be by the production of specific enzymes which perhaps break up the more complex carbohydrates and glucosides into the simpler monosaccharides; these may then be split up by an enzyme common to the whole group. We have endeavoured to judge of the value of Gordon's tests in two ways. In the first place we have repeatedly tested given strains as to the constancy of the reactions displayed, and in the second place we have carefully considered how far differences revealed by the tests are associated with other differences, such as may be shown by cultural and other biological characters, by pathogenic powers, and by distribution in nature.

The constancy of the tests is clearly a cardinal point; unless they can be shown to be reasonably constant their value breaks down at the outset. We have no hesitation in asserting that the reactions are remarkably constant for any given strain of streptococcus, and though we shall have to lay stress on certain exceptions to this rule it will only be for the purpose of discussing the relative value of the different tests in any scheme of classification which may be based on them. This constancy has been tested in several ways. 1. Several different colonies from the original culture have been simultaneously tested. In almost every case the results have been identical, though occasionally the salicin reaction has been at fault in this respect. The chief exceptions have been cases such as perforative peritonitis, in which it is reasonable to suppose that several varieties of the rich flora of the gut have simultaneously escaped into the peritoneum, or such as tonsillitis, where an analogous explanation holds good. 2. Cases have been compared in which it was reasonably certain that different patients had been infected from the same source. Opportunities for such observations are necessarily uncommon but we may quote two instances. A woman was admitted to hospital suffering from puerperal septicæmia, from which she died. From the heart's blood and from the uterus a streptococcus was cultivated which gave positive reactions with saccharose, lactose, salicin, and mannite. Three days later the infant which she had borne succumbed to erysipelas and pyæmia, and from th pus in its wrist-joint a streptococcus was isolated in pur culture, giving reactions identical with those of the materna organism. Again, two children died in hospital within few days of one another, the one from septicæmia associate with cellulitis of the neck and the other from septicæmi associated with a gastro-enteritis due to Gärtner's bacillus I each case a pure culture of a streptococcus was isolated fron the heart's blood, giving the same reactions as those of th mother and child just quoted, and in each case the mannit reaction was lost after a week's subculture on gelatin. I so happened that one of us had tested one case and one th other, and when we came to compare notes, struck by the corresponding loss of the mannite reaction, we discovered that the two patients were brothers, admitted to the hospital during the same week, the one to a medical and the other to a surgical ward. These instances gain in force from the fact that the streptococcus in question is by no means one of the commonest types met with in disease. We regard it, as will appear later, as a variety of streptococcus pyogenes. 3. The tests have been repeated after prolonged subculture, in some cases extending over a year. Here again the results are singularly constant and exceptions are infrequent. One example must suffice. There is a form of intestinal streptococcus growing in short chains, reacting positively to all of Gordon's tests, except raffinose and inulin, and possessing the power of rapidly liquefying gelatin: it is not pathogenic. An old culture left in the incubator for nine months was recently revivified and showed all the old reactions unchanged, including liquefaction of the gelatin. We could give other instances of this pertinacity of type. Nevertheless we must record other cases in which slight differences have been noted. We have already alluded to two cases in which the mannite reaction was speedily lost; in other instances reactions with salicin and neutral red have been both lost and gained; these two latter tests seem indeed more liable to vary than most of the others. 4. We have repeatedly tested the reactions of pathogenic streptococci before and after passage through the mouse, and we can confirm Gordon's statement that the reactions are almost invariably unchanged, though we have once or twice found the salicin reaction to vary. We have on one occasion pursued the same streptococcus through a series of infections. A woman died in hospital from a septicæmia secondary to ulcerative stomatitis. From the blood during life a streptococcus was isolated which grew well on gelatin at 20° C., failed to clot milk, and readily attacked lactose and salicin. It gave a feeble saccharose reaction and by the ninth day (a point far beyond that to which most of our observations extend) coniferin and mannite gave also an acid reaction. From the heart's blood post mortem and from the pus in a knee-joint a streptococcus was grown in pure culture which gave the same reactions. The saccharose reaction was feeble and on this occasion no reactions occurred with coniferin and mannite by the seventh day. One of us (T. J. H.) had the misfortune to prick his finger at reactions are saccharose, lactose, and raffinose, the last-named less constantly than the first two. The glucoside reactions may be added, and rarely inulin.

Streptococcus salivarius is related in many ways to the pneumococci, which may prove to be a pathogenic offshoot from it. It is possible that some of Gordon's specimens from saliva were really pneumococci, but he paid no attention to the question of capsules. Streptococcus salivarius, however, is certainly not identical with the pneumococcus, being for the most part non-pathogenic; the pneumococcus, moreover, very rarely reduces neutral red.

E. This is the pathogenic long-chained form of streptococcus salivarius, and seems to have a special connexion with inflammation of the fauces and with scarlet fever. If, as some maintain, the cause of scarlet fever is a streptococcus, the particular sort of streptococcus is probably to be found within the limits of this group. Our data as regards scarlet fever will be given later and will be found far from conclusive. Meanwhile, since this particular type of streptococcus occurs in other sore-throats, and indeed in the normal alimentary canal, as well as (less commonly) in other diseased conditions, we would suggest the term "*streptococcus anginosus*" as not inapplicable to it.

The characters of streptococcus anginosus are as follows. It is a long-chained form, producing in broth a flocculent deposit like that of streptococcus pyogenes. The differences between it and pyogenes are that, more often than not, it will not grow on gelatin at 20° C., that it is only rarely associated with suppuration, and that it habitually clots milk and reduces neutral red. Nevertheless, a number of its variants fail to clot milk and form transitions to streptococcus pyogenes. We cannot draw a hard and fast line between the two. Like pyogenes, it is markedly hæmolytic. In its chemical reactions it is practically indistinguishable from streptococcus salivarius. The type-reactions are: clotting of milk, reduction of neutral red, and acid formation with saccharose and lactose, to which raffinose is often added. Other variants include the glucosides and in rare cases inulin. This long-chained form is recorded 32 times from the normal throat and intestine and has also been found in the intestine of both carnivora and herbivora. We have met with it 16 times in ordinary diseases and 23 times in disease processes (principally scarlet fever) where we could not feel certain that it was the causal agent.

F. There is a group of streptococci so characteristic of the human intestine that the term "*streptococcus fæcalis*" may justly be applied to it. It is mostly short-chained, rendering broth uniformly turbid, but in disease, at least, forms with long to medium chains occur. It grows readily on gelatin at 20° C. with rare exceptions and is distinguished by its great chemical activity. It forms H_2S in broth cultures but is totally devoid so far as our experiments go, of hæmolytic power. Its chemical powers are rapidly manifested and the typical intestinal form (40 specimens in Houston's 300) reacts positively to Gordon's tests in all cases save raffinose and inulin; even these may be added. A mannite reaction is constant but the variants are very numerous. There are records of 29. Even gelatin may be liquefied by some varieties of the typical form. The species possesses a very great resistance to desiccation, far greater than that of the long-chained throat forms. It is not pathogenic for rodents. This form is not found, according to Gordon, in normal saliva. He never once found a streptococcus fermenting mannite in the 300 colonies which he tested. The mannite test is probably not an absolute one and he found types resembling streptococcus fæcalis in all except this. Nevertheless it seems justifiable to assert that the mannite reaction is characteristic of a large number of intestinal as opposed to salivary streptococci. We have found this type on 13 occasions in disease processes, notably in cystitis, and we regard it as a facultative parasite.

G. There remain the *pneumococci*. We have tested 34 strains in the same way as we have tested the pathogenic streptococci. We have found many varieties, but with one exception we consider that they may all be referred to a single species The one exception is an isolated example only which will be mentioned later. The distinguishing mark of the pneumococci is the possession of a capsule when growing in the animal body and in certain culture media. On ordinary media this capsule is not apparent and the cocci frequently form chains of considerable length, so that there seems no justification for removing the pneumococci from the genus streptococcus.

A critical examination of the seven groups of streptococci above enumerated will at once reveal the fact that the grouping is arbitrary. The different kinds to which we have given names shade off into one another by imperceptible gradations and the view which we have adopted as to variants by suppression and by addition renders it frequently uncertain to which type a given form of streptococcus should be referred. We would meet such criticism in advance with the remark that this indefinite state of affairs actually represents the condition found in nature. We regard the streptococci as a "dominant genus" which has specially adapted itself to a saprophytic existence in the alimentary canal of man and animals. Under the favourable conditions there offered, the food-supply being abundant and highly varied, the genus has, as it were, specialised in metabolic powers so that a great variety of races has sprung up differing in their precise capacities for attacking different foodstuffs. Some of these races have prevailed numerically above their fellows and are on their way to become distinct species though still connected by transitional forms. Further, certain of them have begun to adapt themselves to a truly parasitic existence; some, such as streptococcus pyogenes, have done so with marked success and are already amongst the most formidable bacterial foes with which the body has to contend; others are mere facultative parasites of a much lower degree of virulence.

What we have done in our attempt to sort out the chemical types hitherto recorded has been to select those types which have thus prevailed numerically and to apply names which may serve to indicate them, not perhaps as well-defined species but as species in the making, already so distinct as to deserve special appellations. The less abundant intermediate forms have been fitted in, as well as might be, as variants of the more prominent forms. It is probable that in the present state of our knowledge no more sharply defined classification of the streptococci is possible and that the scheme above outlined fairly represents the actual medley of types seen in nature, and the way in which, by the processes of evolution, nature herself is sorting out the medley. A certain element of arbitrariness is inevitable in any attempt of the kind. Whether the precise criteria we have selected are the best and most fundamental is another matter; we can only plead that we have done our best to introduce some sort of order into what has hitherto been a perplexing maze, and we venture to believe that some such conception of the streptococci as we have set forth is preferable to the idea that they are all one kind or that they present a hopeless chaos.

Having thus set forth the results of the attempted correlation of the varied types of streptococci revealed by the application of Gordon's tests to the 1200 or so specimens recorded, a further criticism may be possible as to the value of those tests. We have shown that their constancy is sufficiently great to warrant reliance upon them. We consider that, in addition, the variations which these tests reveal correspond sufficiently with variations in other characters to make them the best available guide through the labyrinth of forms. We find that we can more readily "place" a streptococcus, and surmise its source and probable virulence, by the aid of Gordon's tests than in any other one way. These tests are capable of good and of bad use. We have given sufficient reason for the belief that in themselves they are too arbitrary for a systematic classification. Probably no one of the nine tests is of absolute and constant worth, while several are certainly of little value. Reliance on these tests alone must result in a purely empirical scheme of classification of little real scientific utility. But taken in conjunction with other characters the tests appear in a very different light and afford a clue to the nature of any given form of streptococcus which is invaluable. The introduction of these tests by Gordon is, in our judgment, the most important advance which has been made in recent years in the study of the streptococci.

(To be continued.)

BRIXHAM COTTAGE HOSPITAL.—Lord Churston is endeavouring to raise £5000 as an endowment for the cottage hospital at Brixham in Devonshire. The population of Brixham consists almost entirely of fishermen and their families, and the cottage hospital performs an admirable work in assisting the men employed in the large fishing fleet, of which Brixham is the headquarters, in cases of accident and sickness. Already over £600 have been promised as a commencement of the fund, and it is hoped that with an effort the full amount will be subscribed.

Here, then, are six different chemical types within the limits of what, on broad general grounds, must be regarded as a single species of streptococcus. No one of the reactions is constant, but the limitation of the *reactions to saccharose* and the glucosides is constant, and the specificity of the group *is emphasised by the absence of an acid reaction* in milk and by inability to grow on gelatin at 20° C. The type, as evidenced by numerical frequency, is clearly number 4. The variants are "variants by suppression" *of one or other reaction. It is probable that there exist* also "variants by addition," for a common air streptococcus shows an inulin reaction added to saccharose, salicin, and coniferin, and another less common one shows addition of both inulin and raffinose (the latter variant having been found once in horsedung). Further, there are closely allied forms which reduce neutral red. The series above adduced illustrates at once the strength and the weakness of Gordon's tests as a specific guide in classification. The weakness is plain when unsupported by other evidence, for a streptococcus giving, for instance, a positive reaction with saccharose only might equally well, as we shall show, be a pneumococcus or a virulent type of streptococcus pyogenes. And the strength is this, that a streptococcus from the mouth fermenting only saccharose, salicin, and coniferin, non-pathogenic, and incapable *of growth on* gelatin at 20° C., may with some confidence be referred to inhaled horse-dung. The series serves also to illustrate the principles of classification which have guided us in our *preliminary* attempts to group the streptococci according to their chemical properties.

Turning now to the 1200 or so specimens of streptococci which have been tabulated from all sources, saprophytes and parasites together, they may be roughly grouped as follows.

A. The saprophytic group above mentioned which seems derived from the herbivorous intestine and may be termed "*streptococcus equinus.*" Its characters have already been sufficiently described; so far as is known it is totally devoid of pathogenic properties. There are records of 152 specimens conforming to the main types (i.e., fermenting only saccharose and the glucosides), derived chiefly from air, dust, and horse-dung, but including 17 from human saliva, 23 from human fæces, and one from urine. The variants which in addition give reactions with raffinose and inulin number 95 specimens (45 from air and dust, and 50 from human fæces and saliva). Variants giving also a neutral red reaction number 29 specimens.

B. The second group is still essentially saprophytic, occurring chiefly in human saliva and fæces, but is occasionally associated with disease. It is a short-chained form capable of good growth on gelatin at 20° C., and it gives a *marked acid reaction in milk, though no clotting.* Further, it almost always ferments lactose. These characters fail to separate it very clearly from Type A, but they do not sharply define it from Type C, the true streptococcus *pyogenes. The only reasons which induce us to separate* Types B and C are that Type B is habitually short-chained and *non-pathogenic, and never associated with suppuration*, while Type C is habitually long-chained, virulent, and typically associated with suppurative processes, being found only occasionally as a saprophyte. These *differences are vague, and we are inclined to regard Type C* as a parasitic *form* which has been *evolved* from Type B and is not yet *sharply separated from it. Type B has been* found with almost equal frequency in saliva and in the intestinal contents. In 132 *specimens it has only nine times* been found associated with disease processes and only once or *twice* has there been *reason for regarding* it as *truly* pathogenic. Such forms may with fair propriety be regarded as variants *of Type D* in which the power of clotting milk has been suppressed. Some name must for convenience be given to this type and we would suggest "*streptococcus mitis*" as a non-committal term fairly expressing its habitually non-virulent character. It may be defined as a short-chained form, almost never pathogenic, inhabiting the human alimentary canal, *growing well* on gelatin at 20° C., not clotting milk but often reducing neutral red. Its typical positive reactions with *Gordon's tests* are saccharose and lactose with or without the glucosides. 58 specimens are recorded as of this *type*; *raffinose* or inulin reactions were also present in 10 further specimens and reduction of neutral red in 64 more. This saprophytic type is of chief interest as the probable form from which the virulent streptococcus pyogenes has arisen.

C. The third group is one of the utmost importance in human pathology, having as its type the classical organism first described by Fehleisen as "streptococcus erysipelatos," but *since* more generally known by Rosenbach's name, "*streptococcus pyogenes.*" We adhere to the latter term because, though Fehleisen's name has undoubted priority, this species does so much more than produce erysipelas that the wider term deserves to supplant the narrower. This type has assumed more definitely parasitic characters than any other sort of streptococcus and in its fully-developed form seems not to occur as a human saprophyte, though some of its variants have been met with in saliva and fæces. Its characters are as follows. It is a long-chained form usually growing in woolly masses at the bottom of a clear broth; occasionally the broth is somewhat turbid and the chains of only medium length. It grows vigorously on gelatin at 20° C. It is actively hæmolytic but does not form H_2S in broth culture. It strongly acidifies milk but never clots it, nor does it reduce neutral red (those allied forms which do so we refer to Type D; they commonly show other differential characters in *addition*). The usual *positive* reactions with Gordon's tests are saccharose, lactose, and salicin, but a variant lacking the salicin reaction is quite common. It is highly pathogenic for the mouse and rabbit, *somewhat less so for the guinea-pig*, though it often produces a local suppuration in this animal. When freshly isolated from a case of human disease it generally produces a fatal septicæmia in the mouse in two or three days. In its commonest form, *giving reactions* with *saccharose*, *lactose*, and salicin, it has been met with 33 times in human disease and *five times doubtfully associated* with *disease processes*, but never as a saprophyte except as a short-chained form (Type B). In one case, of a child suffering from an acute and rapidly fatal pharyngitis, an organism was obtained from the tonsil in almost pure culture which *in all respects* resembled the classical streptococcus pyogenes, save that it rapidly liquefied gelatin.

Any one of the three cardinal reactions may be suppressed, giving variants which we shall describe later in detail. Further, certain reactions may be added, notably mannite or coniferin, without any other change in the general characters of the type. (Variants also occur in which raffinose and inulin reactions are added, but we have some grounds for regarding these as modifications of Type D in which the power of clotting milk has become suppressed.) The variants by suppression and by addition of mannite and coniferin account for 38 cases in which the organism was definitely pathogenic and 15 in which it was otherwise associated with disease processes. 15 such variants are recorded from normal saliva and fæces.

D. There is a form of streptococcus so characteristic of the saliva, though it is also common in the intestine, that the term "*streptococcus salivarius*" may justly be applied to it. It is the form often spoken of as streptococcus brevis of the mouth, but so many other forms are also short-chained that some more distinctive appellation is needed. No less than 211 out of the 300 salivary streptococci studied by Gordon fall under the possible variants of this type and 105 out of Houston's 300 fæcal streptococci (i.e., it is proportionately twice as common in the mouth as in the intestine). Its variants pass by insensible gradations into those of the commonest intestinal form (Type F) which we describe as "streptococcus *fæcalis*," and we are unable to draw any absolute distinction between the two forms. Streptococcus salivarius, *even* in its short-chained form, plays no unimportant part in human pathology, and we have it *recorded* as pathogenic in 26 cases. But it appears to bear the same relation to the much more pathogenic long-chained form which we describe as Type E, that streptococcus mitis does to streptococcus pyogenes. There seems to be no distinction between them other than that the long chained forms are more highly pathogenic. Type E is really a parasitic form of Type D, but it is found much more frequently than streptococcus pyogenes as a saprophyte of the normal alimentary canal of man and animals.

The typical characters of streptococcus salivarius are as follows. It is a short-chained form which usually renders broth uniformly turbid, though sometimes the broth is clear with a deposit of short chains. It grows less constantly than Types B and C upon gelatin at 20° C. *Sometimes* it will grow, but often not. It clots milk almost always and in its typical form reduces neutral red, though variants occur which fail to do this. The characteristic fermentation reactions are saccharose, lactose, and raffinose, the last-named less constantly than the first two. The glucoside reactions may be added, and rarely inulin.

Streptococcus salivarius is related in many ways to the pneumococci, which may prove to be a pathogenic offshoot from it. It is possible that some of Gordon's specimens from saliva were really pneumococci, but he paid no attention to the question of capsules. Streptococcus sallivarius, however, is certainly not identical with the pneumococcus, being for the most part non-pathogenic; the pneumococcus, moreover, very rarely reduces neutral red.

E. This is the pathogenic long-chained form of streptococcus salivarius, and seems to have a special connexion with inflammation of the fauces and with scarlet fever. If, as some maintain, the cause of scarlet fever is a streptococcus, the particular sort of streptococcus is probably to be found within the limits of this group. Our data as regards scarlet fever will be given later and will be found far from conclusive. Meanwhile, since this particular type of streptococcus occurs in other sore-throats, and indeed in the normal alimentary canal, as well as (less commonly) in other diseased conditions, we would suggest the term "*streptococcus anginosus*" as not inapplicable to it.

The characters of streptococcus anginosus are as follows. It is a long-chained form, producing in broth a flocculent deposit like that of streptococcus pyogenes. The differences between it and pyogenes are that, more often than not, it will not grow on gelatin at 20° C., that it is only rarely associated with suppuration, and that it habitually clots milk and reduces neutral red. Nevertheless, a number of its variants fail to clot milk and form transitions to streptococcus pyogenes. We cannot draw a hard and fast line between the two. Like pyogenes, it is markedly hæmolytic. In its chemical reactions it is practically indistinguishable from streptococcus salivarius. The type-reactions are: clotting of milk, reduction of neutral red, and acid formation with saccharose and lactose, to which raffinose is often added. Other variants include the glucosides and in rare cases inulin. This long-chained form is recorded 32 times from the normal throat and intestine and has also been found in the intestine of both carnivora and herbivora. We have met with it 16 times in ordinary diseases and 38 times in disease processes (principally scarlet fever) where we could not feel certain that it was the causal agent.

F. There is a group of streptococci so characteristic of the human intestine that the term "*streptococcus fæcalis*" may justly be applied to it. It is mostly short-chained, rendering broth uniformly turbid, but in disease, at least, forms with long to medium chains occur. It grows readily on gelatin at 20° C. with rare exceptions and is distinguished by its great chemical activity. It forms H_2S in broth cultures but is totally devoid so far as our experiments go, of hæmolytic power. Its chemical powers are rapidly manifested and the typical intestinal *form* (40 specimens in Houston's 300) reacts positively to Gordon's tests in all cases save raffinose and inulin; even these may be added. A mannite reaction is constant but the variants are very numerous. There are records of 29. Even gelatin may be liquefied by some varieties of the typical form. The species possesses a very great resistance to desiccation, far greater than that of the long-chained throat forms. It is not pathogenic for rodents. This form is not found, according to Gordon, in normal saliva. He never once found a streptococcus fermenting mannite in the 300 colonies which he tested. The mannite test is probably not an absolute one and he found types resembling streptococcus fæcalis in all except this. Nevertheless it seems justifiable to assert that the mannite reaction is characteristic of a large number of intestinal as opposed to salivary streptococci. We have found this type on 13 occasions in disease processes, notably in cystitis, and we regard it as a facultative parasite.

G. There remain the *pneumococci*. We have tested 34 strains in the same way as we have tested the pathogenic streptococci. We have found many varieties, but with one exception we consider that they may all be referred to a single species. The one exception is an isolated example only which will be mentioned later. The distinguishing mark of the pneumococci is the possession of a capsule when growing in the animal body and in certain culture media. On ordinary media this capsule is not apparent and the cocci frequently form chains of considerable length, so that there seems no justification for removing the pneumococci from the genus streptococcus.

A critical examination of the seven groups of streptococci above enumerated will at once reveal the fact that the grouping is arbitrary. The different kinds to which we have given names shade off into one another by imperceptible gradations and the view which we have adopted as to variants by suppression and by addition renders it frequently uncertain to which type a given form of streptococcus should be referred. We would meet such criticism in advance with the remark that this indefinite state of affairs actually represents the condition found in nature. We regard the streptococci as a "dominant genus" which has specially adapted itself to a saprophytic existence in the alimentary canal of man and animals. Under the favourable conditions there offered, the food-supply being abundant and highly varied, the genus has, as it were, specialised in metabolic powers so that a great variety of races has sprung up differing in their precise capacities for attacking different foodstuffs. Some of these races have prevailed numerically above their fellows and are on their way to become distinct species though still connected by transitional forms. Further, certain of them have begun to adapt themselves to a truly parasitic existence; some, such as streptococcus pyogenes, have done so with marked success and are already amongst the most formidable bacterial foes with which the body has to contend; others are mere facultative parasites of a much lower degree of virulence.

What we have done in our attempt to sort out the chemical types hitherto recorded has been to select those types which have thus prevailed numerically and to apply names which may serve to indicate them, not perhaps as well-defined species but as species in the making, already so distinct as to deserve special appellations. The less abundant intermediate forms have been fitted in, as well as might be, as variants of the more prominent forms. It is probable that in the present state of our knowledge no more sharply defined classification of the streptococci is possible and that the scheme above outlined fairly represents the actual medley of types seen in nature, and the way in which, by the processes of evolution, nature herself is sorting out the medley. A certain element of arbitrariness is inevitable in any attempt of the kind. Whether the precise criteria we have selected are the best and most fundamental is another matter; we can only plead that we have done our best to introduce some sort of order into what has hitherto been a perplexing maze, and we venture to believe that some such conception of the streptococci as we have set forth is preferable to the idea that they are all one kind or that they present a hopeless chaos.

Having thus set forth the results of the attempted correlation of the varied types of streptococci revealed by the application of Gordon's tests to the 1200 or so specimens recorded, a further criticism may be possible as to the value of those tests. We have shown that their constancy is sufficiently great to warrant reliance upon them. We consider that, in addition, the variations which these tests reveal correspond sufficiently with variations in other characters to make them the best available guide through the labyrinth of forms. We find that we can more readily "place" a streptococcus, and surmise its source and probable virulence, by the aid of Gordon's tests than in any other one way. These tests are capable of good and of bad use. We have given sufficient reason for the belief that in themselves they are too arbitrary for a systematic classification. Probably no one of the nine tests is of absolute and constant worth, while several are certainly of little value. Reliance on these tests alone must result in a purely empirical scheme of classification of little real scientific utility. But taken in conjunction with other characters the tests appear in a very different light and afford a clue to the nature of any given form of streptococus which is invaluable. The introduction of these tests by Gordon is, in our judgment, the most important advance which has been made in recent years in the study of the streptococci.

(To be continued.)

BRIXHAM COTTAGE HOSPITAL.—Lord Churston is endeavouring to raise £5000 as an endowment for the cottage hospital at Brixham in Devonshire. The population of Brixham consists almost entirely of fishermen and their families, and the cottage hospital performs an admirable work in assisting the men employed in the large fishing fleet, of which Brixham is the headquarters, in cases of accident and sickness. Already over £800 have been promised as a commencement of the fund, and it is hoped that with an effort the full amount will be subscribed.

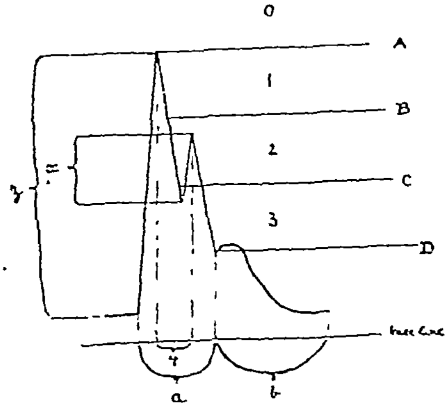
THE PULSE IN AORTIC DISEASE; THE RELATION OF PULSE CURVES TO BLOOD PRESSURE.

BY THOMAS LEWIS, M.B., B.S LOND., M.R.C.S. ENG., L.R.C.P. LOND.,

LATE HOUSE PHYSICIAN, UNIVERSITY COLLEGE HOSPITAL.

An analysis of the pulse curves of 20 cases of aortic regurgitation.—Careful notes were taken of 20 cases of aortic insufficiency. The cases were not selected, but were taken in rotation as they were admitted to hospital. They were examined and the pulse tracings were taken in the majority of cases within two days of admission, when the patients were settled, but before they were under the influence of drugs other than diuretics and purgatives. Most of the physical signs were checked by competent observers; the blood pressures given are average pressures of six or more observations taken for the most part between the hours of 10 A.M. and 12 noon, and at the same time as the tracings. The figures of the pulse analysis are the result of careful measurements and are each an average of five or more analyses from one or more tracings from each radial artery. The chief clinical features are given on the left of the accompanying table. It will be seen that in the majority of the cases they were those of considerable aortic incompetence, that two cases associated had mitral stenosis, and that ten others had mitral regurgitation to a lesser or greater extent. Cases presenting marked signs of aortic stenosis do not occur in the list. Some, no doubt, had a certain degree of stenosis but in no case did the physical signs indicate that it was a prominent feature of the case. Post-mortem examinations were obtained in Cases 6 and 17. Certain lettering and figuring in the table require explanation. Under "sclerosis of arteries," the signs, 0, S, S +, and S + +, indicate normal, slightly sclerosed, sclerosed, and extremely sclerosed vessels respectively. Under "pulsus bisferiens" + signifies its recognition by palpation, ⊕ indicates its presence in marked degree. Under the instrumental analysis the description is divided into systolic and diastolic phases. Referring to Fig. 1, the intervals *a* and *b* are the lengths of systolic and diastolic phases respectively. The "depth of the first notch," x, is given in its relation to the height of the primary wave z. The "second peak position" is given in the table, according to the position of its apex in relation to the equidistant lines A, B, C, and D, where A is drawn through the apex of the primary wave and D through the bottom of the dicrotic notch. In the figure given it falls in the position 2 When the apex falls in the position 0 the pulse is anacrotic When it falls on one of the lines A, B, C, or D it is indicated thus, $\frac{1}{2}$ or $\frac{2}{3}$. The distance separating primary and first secondary wave is given as the distance y, in seconds.

FIG. 1.



The chief points of interest in the table are as follows: 1. 14 cases, of an average age 36·8 years, showed an average systolic blood pressure of 132 mm. Hg (cp Janeway, p. 195). These were cases unassociated with signs of granular kidney. 2. Four cases, with signs of chronic interstitial nephritis and of average age 46 years, showed an average systolic blood pressure of 163 mm. Hg (cp. Janeway, pp. 195 and 169). 3 There was no definite relationship between the height of blood pressure and the amount of arterio-sclerosis (cp. Janeway, p. 185). 4. There was no relationship between the height of blood pressure and the state of compensation (cp. Janeway, p. 199). 5. There were, as would be expected, definite relationships between the amount of sclerosis and the age of the individual and etiology of the case. (Rr = recent rheumatism, So = syphilis of old standing.) 6. With careful palpation a pulsus bisferiens was palpable in 13 cases out of 20, and easily palpable in three cases. It was not palpable where the interval between primary and first secondary waves was less than one-tenth of a second, and not palpable when this interval exceeded one tenth of a second, if the depth of the first notch was limited. 7. There was a definite relationship between the height of the first secondary wave and the amount of arterio-sclerosis. The greater the sclerosis the higher the wave. There was no relationship between the height of the wave and the height of blood pressure and state of compensation. (When the wave occupied position 0 or 1 the pulse felt flat topped; when it occupied position 3 it felt collapsing.) 8 As a rule, though not invariably, the better the compensation the closer were the primary and first secondary wave, and the more shallow was the bisferiens notch (cp Steell). 9. The average duration of systole[1] was 0·38 second, the average duration of diastole was 0·48 second; there was no definite relationship between the two and the relationship was of no prognostic significance (cp. Chapman and Allbutt). 10. A dicrotic notch was present in all cases; in nine cases it appeared normal, in six cases exaggerated, in five cases diminished. In height it showed no definite relationship to the amount of regurgitation (Case 17 in particular), to the height of blood pressure, to the amount of arterio-sclerosis, or the degree of compensation. Neither did it demonstrate any relation to the length of systole, but there was some relation between it and the depth of the bisferiens notch, though this was not constant. 11. In 18 out of 20 cases the two pulse tracings were identical. Of the remaining two, one (Case 6) showed a more prominent pulsus bisferiens on the left side; the other (Case 15) showed it more prominently on the right[2] 12 One case out of 20 showed an anacrotic pulse (Case 2), but only on admission, and on admission compensation was poor; the patient's age was 68 years and he presented signs of extreme arterio-sclerosis and granular kidney.

Types of pulse curves in aortic disease.—The types of tracing met with in aortic stenosis have been fully discussed by many writers, notably by Marey, Mahomed, and Steell. Originally anacrotism was considered to be pathognomonic of the condition; later this type was found in association with numerous other conditions. The pulsus bisferiens was also found in stenotic cases More observations led to the conclusion that neither type is pathognomonic for both may be found apart from stenosis (cp. Steell, &c.). The more recent observers associate anacrotism, combined with low blood pressure, with marked stenosis, and this combination has been confirmed in these investigations by two cases in which the signs were definite; the blood pressures were 110 and 115 respectively

Sansom describes three types of curve met with in cases of regurgitation: (1) curves with large amplitude of upstroke, usually having the dicrotic small and situated low down; (2) anacrotic types, associated with stenosis or renal disease; and (3) normal tracings The second, he states, is of unfavourable prognostic significance, the third of good It is impossible to divide, and indeed it appears inadvisable to attempt to divide, the types into classes. Every intermediate type exists and every combination of them It seems better to describe the main features of these curves and the conclusions which can be drawn from them. In a paper by Galabin on the "water-hammer" pulse emphasis

---

[1] It must not be forgotten that this figure does not include the presphygmic interval (cp Keyt)

[2] W. Broadbent attempted to show that these differences on the two sides are due to the arrangement of the aorta and its branches; in his experience the pulsus bisferiens is generally more marked on the one side This is not the experience of other writers Morison attributes the difference to a difference in longitudinal tension in the vessel investigated, due to the position of the limb The view is not confirmed by these investigations, though it is true that the pulsus bisferiens is better marked with the wrist extended. (Cp. Lewis, Practitioner, 1906.

REMARKS.

CASE 2.—Pulse anacrotic on admission; lost this character in two days.

CASE 4.—Some doubt as to condition of this man's kidneys.

CASE 5.—? Mitral stenosis also.

CASE 6.—Post mortem heart weighed 32 ounces; aorta dilated; muscle substance firm; aorta, chiefly regurg.

CASE 8.—Died shortly after leaving hospital. No necropsy!

CASE 17.—Necropsy. Malignant endocarditis. No trace of aortic valves. Heart weighed 18 ounces.

CASE 18.—? Mitral stenosis also.

was laid on the abrupt primary upstroke (cp. Corrigan). It was shown by him that this feature is the most constant in curves of aortic incompetence and it is referred to by all writers. The abruptness of the upstroke is due to the sudden change from a low diastolic to a high systolic pressure, but it is probable that this character is present in many other conditions, notably high tension of cardiac origin with rapid outflow. Anacrotism has been mentioned already; apart from stenosis it is not commonly met with in aortic disease. In the one case (No. 2) of the 20 tabulated it was only temporary and associated with poor compensation, high blood pressure, and granular kidney (Fig. 2). It was also a feature in the tracings of Case 13 on his second admission, but was present for one day only. The evidence is consequently in support of Sansom's view that it is a sign of failing compensation and has a bad prognostic significance. The height of the first secondary wave has been shown to depend on the condition of the vessel wall. For this reason the anacrotic type should be found where sclerosis is marked (as in Case 2). Four tracings (Figs. 2, 3, 6, and 8) are given, illustrating the height of the second wave, and two others (Figs. 5 and 7) illustrating varying depth of the bisferiens notch. Tracings shown in Figs. 5 and 8 are from the same patient; the type shown in Fig. 5 remained for two days only, during which period the patient showed some heart irregularity.

FIG. 2 (CASE 2).

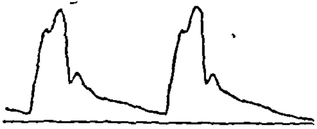

FIG. 3 (CASE 1).

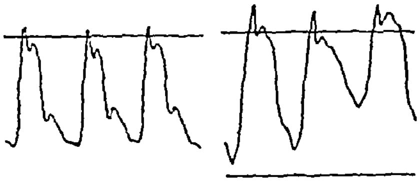

In Fig. 3 a tracing from a thoracic aneurysm (of Case 1) is given (to the right); that to the left is from the radial. The change in the type of pulse during transmission is very slight. In Fig. 4 (Case 2) a very flat-topped type is shown, with the corresponding cardiogram to the right; the change in type during transmission is in this case remarkably small. Pulses of this type never feel collapsing to the finger, though they may be empty between the beats. A collapsing water-hammer pulse is shown in Fig. 8.

In the 20 cases referred to a somewhat inconstant relationship was found between the length of interval between the first and second waves and the prognosis. From these 20 cases and numerous other cases investigated I am inclined to associate the length of this interval with dilatation of the heart; it has never been found of any great length, except in patients with very large hearts (Fig. 7 is from Case 6 and Fig. 5 from Case 12.) As a rule, it is associated with depth of the bisferiens notch but by no means invariably (Fig. 8).

FIG. 4 (CASE 2).

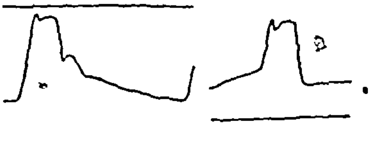

FIG. 5 (CASE 12).

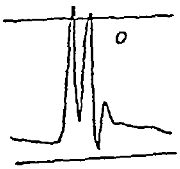

FIG. 6.

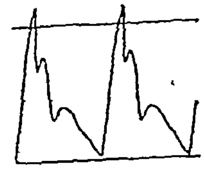

The subject will be referred to later at greater length. The prominence of the dicrotic in the 20 cases investigated is not in accord with the views of earlier writers (cp. Broadbent, Steell, Mahomed, &c.). A partial explanation of this may be due to the fact that the tracings upon which these observations were made were taken at light pressures, for a heavy pressure tends to obliterate the dicrotic or to place it low in the tracing in these cases. It is probable that the dicrotic is present to a normal extent in most aortic cases and it would appear, contrary to the opinion of most writers, that it is of little value in estimating the amount of the regurgitation or the nature of the aortic lesions. That dicrotism depends to some extent on rebound from the aortic valves may be admitted, but, as has been pointed out by Sanderson, Sansom, Galabin, and others, it may be marked where there is free regurgitation (cp. Lewis, *Journal of Physiology* 1906). If further proof of this is required it is to be found in Fig. 10. The dicrotic is well marked, yet post mortem no trace of aortic valves could be found; the case (No. 17) was one of malignant endocarditis. It has been suggested by Galabin that the rebound may in these cases take place from the blood entering the ventricle from the auricle. This is possible, but given a negative pressure in the ventricle during diastole it is somewhat difficult to realise. Moreover, a greater delay might be expected in its appearance at the wrist. By the side of this tracing is another (Fig. 9), showing a feeble dicrotic in a case (No. 10) of free regurgitation.

FIG. 7 (CASE 6).

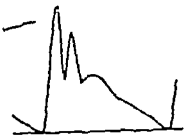

FIG. 8 (CASE 12).

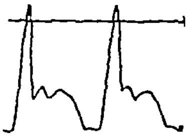

FIG. 9 (CASE 10).

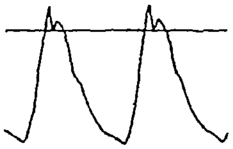

FIG. 10 (CASE 17).

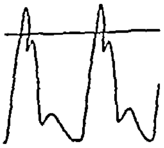

The relation of the height of the first secondary wave to the height of blood pressure.—The difficulty of estimating the height of systolic blood pressure by palpation has only recently been recognised, with the advent of the later and more accurate instruments devised for this purpose.[3] Many prominent writers on the subject of pulse tracings, notably Mahomed, insisted that there is a definite relationship between the height of the first secondary wave and the blood pressure; he estimated it by drawing a line from the apex of the primary wave to the base of the dicrotic notch. He stated that if the first secondary wave was raised above this line abnormal arterial tension was indicated. The methods employed for estimating tension were palpation and the pressure of the sphygmograph pad necessary to obliterate the pulse tracing. Inaccurate method never led to a greater error; it will suffice if a few tracings are given. The first (Fig. 12) a flat-topped pulse in a patient with systolic blood pressure of 115 mm. Hg, and another (Fig. 11) a collapsing pulse from a patient with a systolic pressure of 160 mm. Hg. They are examples

[3] The instruments used in these investigations have been the Dudgeon sphygmograph and C. J. Martin's modified Riva Rocci sphygmomanometer.

of over 20 observations on each of these patients. In the table of aortic cases there is evidence to show this absence of relation, and evidence showing the presence of a relation between arterio-sclerosis and the height of the secondary wave. The patient whose tracing is shown in Fig. 11 suffered from chronic emphysema and presented little arterio-sclerosis. The subject of the tracing in Fig. 12 had marked sclerosis. The want of relation between arterial disease and high blood pressure has already been referred to. The general fall of the writing style from the apex of the pulse curve depends on two factors—the condition of the arterial wall and the rate of outflow. The two tracings shown in Fig. 13 were taken from cases of generalised arterio-sclerosis, the first with a blood pressure of 130 millimetres, the second associated with granular kidney and a pressure of 250 millimetres—yet the two tracings are practically identical.

THE RASH IN CEREBRO-SPINAL MENINGITIS.

BY WILLIAM WRIGHT, M.D. GLASG., D.P.H. CANTAB.,
SENIOR ASSISTANT MEDICAL OFFICER OF HEALTH, GLASGOW.

IN only a few of the numerous cases of the above disease which have occurred in Glasgow since the first quarter of the year has a rash appeared. This is in accordance with the reports of similar epidemics from various quarters in Britain. Herpes has been noticed in several and is usually situated at the angles of the mouth. But it is in regard to those cases in which a definite rash has appeared on the body before death that I desire to call attention. In two a decided purpuric rash, purple in colour and hæmorrhagic in character as spots, with well-demarcated edges, varying in size from a pin head to rather smaller than a lentil, were seen closely packed on the dorsum of the feet and nowhere else on the body. In another in which death took place within 16 hours from the time of onset (the first symptom being that of delirium, the child waking at 4 A.M. in this condition) a well-marked punctate hæmorrhagic rash, each spot singly of the size of a pin head, and in places in clusters of six or seven, was seen scattered all over the trunk and limbs. In another in which death took place after 24 days' illness a rash appeared on the seventh day and from the subsequent history evidently came in crops. On examination on the twenty-first day of the illness, purple and maroon spots, circular, with regular edges all the same size—i.e., that of a lentil—were seen on the dorsum of the feet, on the arms, the legs, the trunk (back and front), four below the chin, and one behind each ear. They were scattered over the body with areas of three to four inches of normal skin between each. These spots were definitely hæmorrhagic in character and so well defined as to be seen from a considerable distance, the picture presenting quite the aspect of "spotted fever." A cluster of 15 maroon spots occupied the interscapular space and appeared on the previous day. On visiting the case the following day those spots previously maroon had changed to purple, were still of the same size, circular with regular edges, but now quite purple. Next day—i.e., the twenty-third day of the illness—they had almost disappeared and fresh maroon ones were seen in other situations. Larger pale-blue blotches with irregular edges fading into the surrounding tissues, 16 in number, were also noticed on the trunk and limbs. They occupied the cutis vera, normal skin could be seen distinctly over them, and at no time was any alteration in their colour, appearance, or position noted.

Glasgow.

A NEW METHOD OF ADMINISTERING AN ANÆSTHETIC THROUGH A TRACHEOTOMY TUBE.

BY WALTER P. COOKLE, M.D. DUB.,
ANÆSTHETIST TO THE METROPOLITAN EAR, NOSE, AND THROAT HOSPITAL.

THOSE of us who are called upon to administer an anæsthetic to a patient through a tracheotomy tube, whether the operation be for laryngotomy, thyrotomy, or other operation requiring a preliminary tracheotomy, have usually adopted one or other of the following methods—namely, a small catheter attached to a Junker's apparatus, a flexible tube and funnel (Hahn's), or a Skinner's mask held over the tracheotomy tube at a suitable distance. The objection to the first two methods is that they tend more or less to obstruct the already diminished air-way, which is one of the great difficulties in the way of administering an anæsthetic in these cases. The presence of a tracheotomy tube in the trachea is already a narrowing of the passage; if anything further, as a catheter, be introduced into this it means a further narrowing; or should respiration be carried on through a long tube the case is even worse—and add to this the deleterious effect of chloroform on respiration and the danger to the patient becomes enormously increased. With regard to the Skinner's mask, the size of the thing itself and the hand of the anæsthetist, taken in conjunction with the smallness of the field for operation, must hamper the movements of the surgeon considerably. Even in the Trendelenburg position the gain in room is not sufficient entirely to counteract these objections. With respect to charging up a patient with chloroform in these cases, to my mind it is a practice to be condemned as fraught with much danger; besides, the patient keeps coming round, often at inconvenient times for the surgeon. With a view to overcoming these difficulties I have had an instrument made for me by Messrs. Hockin, Wilson, and Co. The total length of the instrument is about 15 inches and it is composed of a handle, F G, and a long arm, F E D C B to A. The latter is of flexible metal from D to A and is bent as illustrated. A is a one and a half inches square frame, which is to be covered with lint held in position by a safety-pin or stitching.

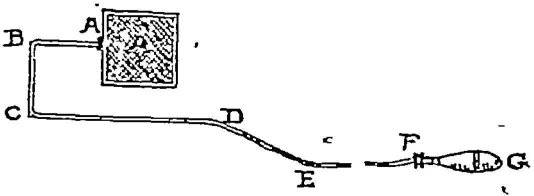

Diagram of Inhaler.

To use the instrument a piece of lint or similar material is stretched across the square A so as to cover it above and below and held in place by means of a safety-pin. Chloroform or O.E. is sprinkled on this from a drop-bottle and the part B C is rested on the sternum of the patient, so that A is above the tracheotomy tube. The limb C D to E is so bent as to bring the point E well down towards the operation table out of the way of the surgeon; E F gradually sloping up and bringing G to about the level of the patient's ear. The length of the instrument enables the anæsthetist to stand well back while using it. The square A was laid on the abrupt primary upstroke (cp. Corrigan). It was shown by him that this feature is the most constant in curves of aortic incompetence and it is referred to by all writers. The abruptness of the upstroke is due to the sudden change from a low diastolic to a high systolic pressure, but it is probable that this character is present in many other conditions, notably high tension of cardiac origin with rapid outflow. Anacrotism has been mentioned already; apart from stenosis it is not commonly met with in aortic disease. In the one case (No. 2) of the 20 tabulated it was only temporary and associated with poor compensation, high blood pressure, and granular kidney (*Fig. 2*). It was also a feature in the tracings of Case 13 on his second admission, but was present for one day only. The evidence is consequently in support of Sansom's view that it is a sign of failing compensation and has a bad prognostic significance. The height of the first secondary wave has been shown to depend on the condition of the vessel wall. For this reason the anacrotic type should be found where sclerosis is marked (as in Case 2). Four tracings (Figs. 2, 3, 6, and 8) are given, illustrating the height of the second wave, and two others (Figs. 5 and 7) illustrating varying depth of the bisferiens notch. Tracings shown in Figs. 5 and 8 are from the same patient; the type shown in Fig. 5 remained for two days only, during which period the patient showed some heart irregularity.

FIG. 2 (CASE 2).

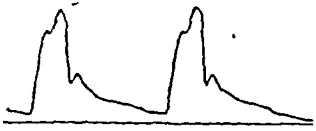

FIG. 3 (CASE 1).

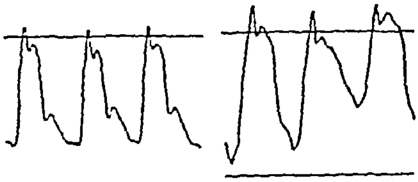

In Fig. 3 a tracing from a thoracic aneurysm (of Case 1) is given (to the right); that to the left is from the radial. The change in the type of pulse during transmission is very slight. In Fig. 4 (Case 2) a very flat-topped type is shown, with the corresponding cardiogram to the right; the change in type during transmission is in this case remarkably small. Pulses of this type never feel collapsing to the finger, though they may be empty between the beats. A collapsing water-hammer pulse is shown in Fig. 8.

In the 20 cases referred to a somewhat inconstant relationship was found between the length of interval between the first and second waves and the prognosis. From these 20 cases and numerous other cases investigated I am inclined to associate the length of this interval with dilatation of the heart; it has never been found of any great length, except in patients with very large hearts (Fig. 7 is from Case 6 and Fig. 5 from Case 12.) As a rule, it is associated with depth of the bisferiens notch but by no means invariably (*Fig. 8*).

FIG. 4 (CASE 2).

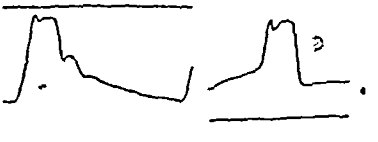

FIG. 5 (CASE 12).

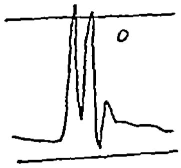

FIG. 6.

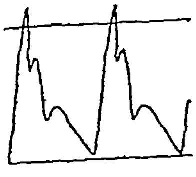

The subject will be referred to later at greater length. The prominence of the dicrotic in the 20 cases investigated is not in accord with the views of earlier writers (cp. Broadbent, Steell, Mahomed, &c.). A partial explanation of this may be due to the fact that the tracings upon which these observations were made were taken at light pressures, for a heavy pressure tends to obliterate the dicrotic or to place it low in the tracing in these cases. It is probable that the dicrotic is present to a normal extent in most aortic cases and it would appear, contrary to the opinion of most writers, that it is of little value in estimating the amount of the regurgitation or the nature of the aortic lesions. That dicrotism depends to some extent on rebound from the aortic valves may be admitted, but, as has been pointed out by Sanderson, Sansom, Galabin, and others, it may be marked where there is free regurgitation (cp. Lewis, *Journal of Physiology* 1906). If further proof of this is required it is to be found in Fig. 10. The dicrotic is well marked, yet post mortem no trace of aortic valves could be found; the case (No. 17) was one of malignant endocarditis. It has been suggested by Galabin that the rebound may in these cases take place from the blood entering the ventricle from the auricle. This is possible, but given a negative pressure in the ventricle during diastole it is somewhat difficult to realise. Moreover, a greater delay might be expected in its appearance at the wrist. By the side of this tracing is another (Fig. 9), showing a feeble dicrotic in a case (No. 10) of free regurgitation.

FIG. 7 (CASE 6).

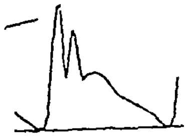

FIG. 8 (CASE 12).

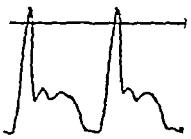

FIG. 9 (CASE 10).

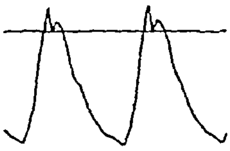

FIG. 10 (CASE 17).

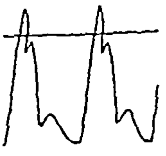

The relation of the height of the first secondary wave to the height of blood pressure.—The difficulty of estimating the height of systolic blood pressure by palpation has only recently been recognised, with the advent of the later and more accurate instruments devised for this purpose.[3] Many prominent writers on the subject of pulse tracings, notably Mahomed, insisted that there is a definite relationship between the height of the first secondary wave and the blood pressure; he estimated it by drawing a line from the apex of the primary wave to the base of the dicrotic notch. He stated that if the first secondary wave was raised above this line abnormal arterial tension was indicated. The methods employed for estimating tension were palpation and the pressure of the sphygmograph pad necessary to obliterate the pulse tracing. Inaccurate method never led to a greater error; it will suffice if a few tracings are given. The first (Fig. 12) a flat-topped pulse in a patient with systolic blood pressure of 115 mm. Hg, and another (Fig. 11) a collapsing pulse from a patient with a systolic pressure of 160 mm. Hg. They are examples

FIG. 11.

---

[3] The instruments used in these investigations have been the Dudgeon sphygmograph and C. J. Martin's modified Riva-Rocci sphygmomanometer.

of over 20 observations on each of these patients. In the table of aortic cases there is evidence to show this absence of relation, and evidence showing the presence of a relation between arterio-sclerosis and the height of the secondary wave. The patient whose tracing is shown in Fig. 11 suffered from chronic emphysema and presented little arterio-sclerosis. The subject of the tracing in Fig. 12 had marked sclerosis. The want of relation between arterial disease and high blood pressure has already been referred to. The general fall of the writing style from the apex of the pulse curve depends on two factors—the condition of the arterial wall and the rate of outflow. The two tracings shown in Fig. 13 were taken from cases of generalised arterio-sclerosis, the first with a blood pressure of 130 millimetres, the second associated with granular kidney and a pressure of 250 millimetres—yet the two tracings are practically identical.

THE RASH IN CEREBRO-SPINAL MENINGITIS.

BY WILLIAM WRIGHT, M.D. GLASG., D.P.H. CANTAB.,
SENIOR ASSISTANT MEDICAL OFFICER OF HEALTH, GLASGOW.

IN only a few of the numerous cases of the above disease which have occurred in Glasgow since the first quarter of the year has a rash appeared. This is in accordance with the reports of similar epidemics from various quarters in Britain. Herpes has been noticed in several and is usually situated at the angles of the mouth. But it is in regard to those cases in which a definite rash has appeared on the body before death that I desire to call attention. In two a decided purpuric rash, purple in colour and hæmorrhagic in character as spots, with well-demarcated edges, varying in size from a pin head to rather smaller than a lentil, were seen closely packed on the dorsum of the feet and nowhere else on the body. In another in which death took place within 16 hours from the time of onset (the first symptom being that of delirium, the child waking at 4 A.M. in this condition) a well-marked punctate hæmorrhagic rash, each spot singly of the size of a pin head, and in places in clusters of six or seven, was seen scattered all over the trunk and limbs. In another in which death took place after 24 days' illness a rash appeared on the seventh day and *from the* subsequent history evidently came in crops. On examination on the twenty-first day of the *illness*, purple and maroon spots, circular, with regular edges all the same size—i.e., that of a lentil—were seen on the dorsum of the feet, on the arms, the legs, the trunk (back and front), four below the chin, and one behind each ear. They were scattered over the body with areas of three to four inches of normal skin between each. These *spots* were definitely hæmorrhagic in character and so well defined as to be seen from a considerable distance, the picture presenting quite the aspect of "spotted fever." A *cluster of* 15 maroon spots occupied the interscapular space and appeared on the previous day. On visiting the case the following day those spots previously maroon had changed to purple, were still of the same size, circular with regular edges, but now quite purple. Next day—i.e., the twenty-third day of the illness—they had almost disappeared and fresh maroon ones were seen in other situations. Larger pale-blue blotches with irregular edges fading into the surrounding tissues, 16 in number, were also noticed on the trunk and limbs. They occupied the cutis vera, normal skin could be seen distinctly over them, and at no time was any alteration in their colour, appearance, or position noted.

Glasgow.

A NEW METHOD OF ADMINISTERING AN ANÆSTHETIC THROUGH A TRACHEOTOMY TUBE.

BY WALTER P. COOKLE, M.D. DUB.,
ANÆSTHETIST TO THE METROPOLITAN EAR, NOSE, AND THROAT HOSPITAL.

THOSE of us who are called upon to administer an anæsthetic to a patient through a tracheotomy tube, whether the operation be for laryngotomy, thyrotomy, or other operation requiring a preliminary tracheotomy, have usually adopted one or other of the following methods—namely, a small catheter attached to a Junker's apparatus, a flexible tube and funnel (Hahn's), or a Skinner's mask held over the tracheotomy tube at a suitable distance. The objection to the first two methods is that they tend more or less to obstruct the already diminished air-way, which is one of the great difficulties in the way of administering an anæsthetic in these cases. The presence of a tracheotomy tube in the trachea is already a narrowing of the passage; if anything further, as a catheter, be introduced into this it means a further narrowing; or should respiration be carried on through a long tube the case is even worse—and add to this the deleterious effect of chloroform on respiration and the danger to the patient becomes enormously increased. With regard to the Skinner's mask, the size of the thing itself and the hand of the anæsthetist, *taken in conjunction* with the smallness of the field for operation, must hamper the movements of the surgeon considerably. Even in the Trendelenburg position the gain *in room* is not sufficient entirely to counteract these objections. With respect to charging up a patient with chloroform in these cases, to my mind it is a practice to be condemned as fraught with much danger; besides, the patient keeps coming round, *often* at inconvenient times for the surgeon. With a view to overcoming these difficulties I have had an instrument made for me by Messrs. Hockin, Wilson, and Co. The *total length* of the instrument is about 15 inches and it is composed of a handle, F G, and a long arm, F E D C B to A. The latter is of flexible metal from D to A and is bent as illustrated. A is a one and a half inches square frame, which is to be covered with lint held in position by a safety-pin or stitching.

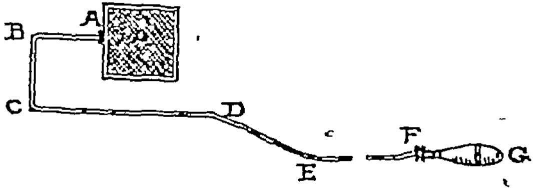

Diagram of Inhaler.

To use the instrument a piece of lint or similar material is stretched across the square A so as to cover it above and below and held in place by means of a safety-pin. Chloroform or C.E. *is sprinkled* on this from a drop-bottle and the part B C is rested on the sternum *of the* patient, so that A is above the tracheotomy tube. The limb C D to E is so bent as *to bring the* point E well down towards the operation table out of the way of *the* surgeon; E F gradually sloping up and bringing G to about the level of the *patient's ear. The length of the* instrument enables the anæsthetist to stand well back while using it. The square A can be raised or lowered over the tracheal opening in two ways—first, as the metal at B is flexible it should be bent up to an angle of about 30°; and secondly, using C B resting on the sternum as a fulcrum by merely raising or lowering the handle F G the distance of A above the tracheotomy tube can be easily adjusted from time to time, to whatever extent desired, according as less or more chloroform is to be given.

In order to replenish the anæsthetic it can either be sprinkled on the lint while *in situ* from a drop-bottle or the whole instrument can be withdrawn sideways for the purpose without trouble. The double lint on the square frame takes a good charge of the anæsthetic and being double and sloping downwards towards the sternum the liquid does not tend to drop on to the tracheal opening should too much accidentally run out. By this method the air-way is not encumbered and feathers can be passed into the tube at any time.

I will quote a case in which I used a model of this instrument and where, I am sure, the patient could never have stood a catheter or tube introduced into the tracheal opening.

The patient, a boy, aged two and a half years, had total occlusion of the larynx due to papillomata, and was sent to hospital for operation. A tracheotomy had been performed some time previously, and through this opening the child breathed fairly well, but the pulse intermitted about every third beat. I anæsthetised the patient with chloroform in the first instance—he appeared to take it well. However, just before the operation was begun the breathing became bad, so I changed to ether, and as it improved to O.E., gradually increasing chloroform until finally anæsthesia was maintained by chloroform alone—using the same instrument throughout. The first incision was made during the O.E administration and the operation was proceeded with. It was curious to note how as the patient took more and more of the anæsthetic he became inured to it, for after half an hour he took pure chloroform without any unfavourable effect whatever either on respiration or the heart; he breathed freely, kept quite warm, and the face was a good colour all the time. Altogether he was under the anæsthetic three and a quarter hours, six drachms of chloroform being used and about three ounces of ether. There was no interruption of any kind during the operation. By adopting this method the patient had the full benefit of the calibre of the tracheotomy tube as a medium for respiration. There was no resistance to expiration; the miniature mask is not cup-shaped but perfectly flat and was never nearer to the tracheal opening when charged with chloroform than about one and a half inches, thus allowing a good outlet during expiration—which is, I think, of more importance than is generally supposed—as well as allowing a desirable proportion of air to mix with the anæsthetic prior to inhalation.

Should the operator and his assistants desire to take full possession of the head and neck of the patient and the anæsthetist, having put the patient under, be required for this purpose to continue the anæsthetic from the other end of the couch, this can be easily accomplished by inverting the instrument and extending the frame carrying the lint about 150°. By this means, and still resting B C—which for simplicity I may call the cross-bar or sternum piece of the instrument—on the sternum, the whole can be manipulated in precisely the same manner as before—that is to say, by raising or lowering the handle the mask is lowered or raised at will. In the case I have just quoted it was not necessary to adopt this course, as when the surgeon wanted to work from above or to obtain a good view downwards from the head to the larynx it was possible for him to obtain his wishes during a brief interval in which the anæsthetic was suspended.

One word of warning is perhaps necessary in the use of this instrument, and it is that while the surgeon is engrossed in his work he may inadvertently rest his arm on the lint-covered frame and press it down over the tracheotomy tube, but this can easily be guarded against by observing when he is going to adopt that position and moving the instrument out of his way for the time.

The advantages to be derived from this method may be summarised as follows: (1) It administers chloroform or O.E. efficiently; (2) practically it does not interfere with the surgeon at all; (3) it gives the surgeon the maximum space possible; (4) it is much safer than a tube and funnel or catheter and Junker arrangement, and it is not so cumbersome and obtrusive as a Skinner's mask; (5) it is cheap, durable, and easily sterilised; (6) it is flexible and can be accommodated to any position to regulate the quantity of anæsthetic given; (7) in case of necessity it will administer ether alone as a stimulant; and (8) it can be used from any position to suit the surgeon.

Ealing, W.

ANKYLOSTOME PARASITISM AMONG THE NATIVE LABOURERS IN THE TRANSVAAL.

By W. G. TOTTENHAM POSNETT, F.R.C.S. IREL.,

HONORARY PATHOLOGIST TO THE JOHANNESBURG HOSPITAL.

WHILE acting as medical officer in charge of the Johannesburg Prison from March to August, 1904, I noticed that many of the natives under my care were suffering from anæmia, some to a slight degree, others showing marked blanching of the mucous membranes, though, like all natives, they did not report themselves sick until they were in a serious condition. One morning the head warder in charge of the native section of the gaol sent a "boy" up to the hospital as he seemed ill, and on my rounds I saw him and made the following note of his condition. He was a tall well-nourished "boy" (Shangaan). The mucous membranes were almost white, the respirations (while standing) were 29, the temperature was 97·4°F., and the pulse was 112. There was great cardiac distress, with diffuse præcordial pulsation. When asked where he was sick he pointed to his epigastrium. Suspecting ankylostomiasis, though never having heard that the disease occurred among the natives here, I examined a portion of his stool microscopically and found numerous eggs of the ankylostomum duodenale. Being very busy at the time I was unable to investigate the case further but the "boy" got quite well under the usual thymol treatment.

Since being appointed honorary pathologist on the staff of the Johannesburg Hospital I have had more opportunities of following up the idea that I had formed that the natives were extensively infected with ankylostomes. This surmise has been borne out by the investigation of some 40 specimens of the stools of natives admitted for various diseases to the native medical ward of the hospital. The "boys" from whom the specimens were obtained belong to the many and various tribes which inhabit South Africa, south of Rhodesia, and including Portuguese East Africa. Out of the 40 specimens of fæces subjected to microscopical observation 32 per cent. contained the ova of the ankylostome. None of these natives showed symptoms of ankylostomiasis. I noticed that the natives from Portuguese East Africa and the Shangaans from the low veldt were more frequently the hosts of the parasite than the members of other tribes. This parasite is therefore evidently widely distributed throughout the natives employed on the mines of the Witwatersrand and such being the case the economic importance of its recognition to the mining community of these fields cannot be passed over in a light manner. Although not as a rule, so far as I can find out, a direct cause of death among the natives of the mines its debilitating presence must be counted as a serious factor in the high death-rate prevailing among our native labourers. But the importance of this parasitic nematode worm being a very frequent inhabitant of the intestines of our coloured workmen does not end with the native—we have to think of our white miners as well.

From information imparted by old miners on the Rand it is evident that the sanitary conditions underground on the mines during the time of the South African Republic were in a most primitive condition, consequently the native evacuated his intestinal contents anywhere and everywhere in the workings, thus contaminating the ground with a most dangerously infective host of ova of the ankylostome. The white miner was far from innocent in the same respect. It is therefore a foregone conclusion that our white miners must be extensively infected by ankylostome parasites, and, although they may not show any symptoms of doing so, their working capacity and illness-resisting powers must be considerably reduced. Unfortunately, I am not in a position to be able to obtain the necessary material for a microscopical search of the white miners' intestinal parasites so as to prove the above assumption, but I do not doubt its correctness. In 1902 Haldane and Boycott were sent to investigate miners' anæmia in Cornwall with the result of finding the ankylostome to be the cause. In 1899 the Boer war broke out and as a consequence thousands of Cornish miners and miners from other parts of England, Scotland, and Wales were forced to leave the Transvaal and return home until the end of hostilities. A large number of these men found work in the mines of the old country, and the assumption forces itself upon me that these miners, importing large numbers of ankylostome ova, must have been a large factor in increasing the infection already existing among their fellow workmen, hence the symptoms which called for the investigation conducted by Haldane and Boycott.

The disposal of sewage created by a community, a large proportion of which are hosts of the ankylostomum duodenale, must be carefully considered by those in charge of the health of the inhabitants of localities where such occurs. If sewage farming be adopted the dissemination of the infecting larva by means of lettuce, radishes, and other vegetables which are eaten in an uncooked condition is very liable to occur. The septic tank system commends itself to me as being that most likely to destroy the infecting agent, unless running the sewage out to sea be available. I believe it has fallen to my lot to be the first[1] to point out the existence of ankylostome infection among the natives of the Rand, but the more complete research into the infection of white miners I must leave to those whose opportunities, as medical officers of the various mines, are almost unlimited and whose time is not occupied by the uncertainties of general practice.

Johannesburg.

URINARY CALCULUS AND ITS DETECTION WITH THE X RAYS.

By EDWARD W. H. SHENTON, M.R.C.S. Eng., L.R.C.P. Lond.,

RADIOGRAPHER TO GUY'S, ST. PETER'S, AND THE HAMPSTEAD GENERAL HOSPITALS.

I BELIEVE that there is a very general misconception with regard to the proper uses of the x rays in the detection of urinary calculus. This opinion has been forced upon me by the reading of the little literature there is on this subject, and by conversation with practitioners who are interested in the results but are not conversant with the means by which diagnosis is attained in renal radiography. To put the matter briefly, it is not recognised that there are two ways in which the rays may be used, first, for screen examination and, second, for photographic effect, and beyond question the *former* is the one of service in diagnosing lithiasis. I make this statement after a full and deliberate consideration of the subject for upwards of nine years. It is worthy of note that, whenever or wherever a surgeon reports a case in which the x rays have been *used*, he always says "the radiogram showed this or that" and never "the screen examination" It is not to be wondered, therefore, that one hears continually of the "deceptiveness of skiagrams" and "expert interpretations of radiograms," &c For the last two years in my own practice I have used radiograms as the microscopist would use photography as a means of recording what has already been seen and as a reference when examining other cases.

There is little doubt that improvement in methods and apparatus is largely responsible for the better screening capabilities of the x rays but this does not tell the whole story. The active x rays—by which I mean the x rays as they illumine the screen—constitute a potent diagnostic instrument, and if we will concentrate our attention upon the shadows they throw of the living organs we can train ourselves to see much that will be of use to us as medical men. It has been truly said, "we see what we are taught to see," and the converse holds good in that if we are not shown a thing we do not see it, or at any rate are remarkably slow to appreciate its presence. It is only after watching a screen daily for many years that the x ray operator has at last had forced upon his notice facts that are of inestimable value to him as a diagnostician. The same may doubtlessly be said of many other forms of diagnosis; it must have surely been a long time before the first users of auscultation found out how to sift and classify the sounds they heard and knew which were normal and which were not. With the screen examination of other regions of the body save those containing the urinary organs we are not concerned in this article, but these regions, the abdomen and pelvis, must be specially considered. There is, I regret to say, a general tendency to invent complicated apparatus for obtaining abdominal skiagrams—machines that cut the current off during a portion of a breath, apparatus that exerts pressure on or around a kidney to hold it still, &c., and no extra care is being bestowed upon the obviously efficient and invaluable screen. If anyone will take a little trouble and study the screening method I am about to describe I feel convinced he will be surprised, firstly, at how little he can see; secondly, at how much, and what assurance he will feel as to the presence of a stone when once he has seen it *in situ* upon the screen, and not as a mere smudgy mark upon a dismal-looking radiogram. I would not do away with radiography, for by its means much useful and confirmatory evidence in urinary cases is forthcoming, but it should be clearly understood that because an object is not visible in a photograph it is not necessarily absent in the subject photographed—the skiagram may be too bad; or—and this also is very likely—it may be too good. It should be generally understood that if a skiagram, particularly of the lumbar regions, possesses great pictorial beauty, a clear spine with a few well-defined and clear cut ribs, it is usually inadequate so far as diagnostic value is concerned. Pale stones, such as phosphatic calculi, and little stones will not appear, and to show these it is essential to get a dull grey image which, from a pictorial point of view, is unattractive. I am told by certain radiographers that surgeons will not receive these pictures but insist upon a bright cheerful skiagram which shows nothing useful, and to clinch the argument I have been shown splendid photographs taken by a local pharmaceutical chemist or instrument-maker showing a black well-defined calculus, and told that is how surgeons like their calculi shown. Now I venture to think that these radiographic experts are to blame for not properly enlightening the surgeon in this matter. It is not usual to blame the physician because a heart bruit is not as loud in one particular case as in another, and we do not usually suggest that if he cannot make this bruit louder we shall be forced to go elsewhere for our consultant. Is there, therefore, any more sense in blaming the radiographer because he only shows a faint shadow in a photograph when by its mere showing he can tell you three important facts—firstly, the presence of a stone; secondly, its quality; and thirdly, its anatomical position? Is it reasonable to hold up to him the record of a powerful x ray obstructing oxalate stone which no amount of skill would prevent from throwing its shadow on a photographic plate and which therefore is an ideal subject for the lay x rayist, and tell him that he must make all his uric acid stones appear the same? Then the surgeon will occasionally say: "I had a good x ray photograph taken of the patient but it showed no stone." Just so; and if he had had a good screen examination followed by what he would call a poor photograph he would have had much useful and sensible information which would have served him better than his stone-obliterating but pictorially excellent radiogram.

Another difficulty the surgeon unintentionally puts in the radiographer's path is the following. He must have a skiagram of large dimensions and the larger the area the more accuracy he imagines he is getting. In this matter he is totally wrong and if he would spare a little time and watch the effects of a contracting diaphragm on a given screen image he would quickly appreciate the fault. Increasing the size of a radiogram is like throwing extraneous light upon a magic lantern picture, the excellence of the latter being in inverse proportion to the quantity of extraneous light thrown. Or, to use a photographic simile, the difference between an unstopped and stopped lens is the difference in effect between the large radiogram and the small. Now, if we have a large radiogram of the abdominal region, including both kidneys, ribs, and crest of ilia, we succeed in excluding all but the most opaque and obtrusive stones, and a little experimenting with a few small calculi laid upon a patient under x ray examination will at once prove this fact. One striking case of this kind I might mention was when the open tube showed no calculus, a large diaphragm demonstrated a small elusive shadow in the left kidney region, and by contracting the diaphragm until it was only just larger than the little shadow a calculus was observed the outline of which was clean cut and clearly defined; the photograph which I took measures about one and a half inches square. "The smaller the diaphragm the better the skiagram," would be a true maxim if it were borne in mind that the actual image does not become smaller, and therefore the diaphragm must be sufficiently large to include the object examined. We have no method of reducing the size of our image as in photography, for the x rays cannot be refracted, reflected, or influenced in any such way. Now it would be very laborious and well-nigh impossible to take a quantity of little skiagrams about one and a half inches in diameter all over the urinary areas, and it is, therefore, to the screen that we must turn for assistance. In a screen examination it is possible to examine the patient in a series of small areas and in this lies one of the superiorities of screening over photography. Moreover, the amount of movement constantly present in the abdomen, whatever precautions are taken, such as holding the breath, fixing the kidney with compressors, &c., makes photography in small areas often of little use, whereas the slight movement upon the screen is a positive help in the detection of a foreign body.

---

[1] Transvaal Medical Journal, April 1st, 1906.

It may be of interest to the reader if I give a brief description of the routine examination of a patient suspected of urinary calculus, the principle being one I have employed with more or less success in the examination of over 1600 cases. The source of light should be below and the screen above. This is effected by the patient lying on a table with a canvas top. He lies upon his face, for in this position the abdomen is reduced in antero-posterior measurement. The screen is placed upon his back. The tube from the first should be shaded by a diaphragm of some x ray opaque material—metal or a special kind of indiarubber. The opening in this diaphragm should not be more than four inches if variable or three inches if fixed and the tube is brought as close to the patient as is consistent with comfort. This will probably be three or four inches from the skin—if much nearer the high tension current is perceptible and causes more or less discomfort; it is not, however, painful or dangerous from this part of the tube. Now we come to an important consideration and that is the difficulty of seeing an image upon the screen through this thick part of the body. It is essential that the operator shall have been at least 15 minutes in the darkened room before he can fully appreciate the screen picture, and one has only to go into a dark room from bright daylight and wait to realise the enormous facility the eye has of adapting itself to varying degrees of illumination if given sufficient time, and how in a few minutes the apparently dark room becomes more and more a room of subdued light only. Coming from ordinary daylight to look at the screen in a quite dark room the operator's vision will slowly and steadily improve for quite 15 minutes. There is no doubt, however, that confinement in a dark room is very tedious and unattractive to a busy man and I have overcome this difficulty in the following manner. The screen image is, as most people are aware, yellow usually, but sometimes slightly greenish. I have therefore lighted the operating room with the complementary colour—in my own case a blue light, and this, though ample light for most purposes, leaves the retina immediately ready to receive the yellow screen light. I would particularly call attention to this matter as it has been a great comfort and for me an important feature in connexion with screen examination.

What one observes first of all upon the screen is a dim circle of light and this by suitable mechanism is adjusted in the middle line until the individual lumbar vertebræ are discernible. Then it is well to look for the transverse processes. If these are clearly seen the operator may feel assured that no calculus of reasonable size or of suitable chemical consistency will succeed in eluding detection. A diligent search is now commenced, by moving the tube over the renal areas, for any suspicious-looking body. It is curious how with practice a foreign object, such as a calculus, arrests the attention. Upon discerning the slightest suspicion of a foreign body the patient is told to take a deep breath. This is done for two reasons: first, a moving body is often easier to detect than one remaining stationary; and secondly, the relative movements of this object and surrounding organs bear an important relation to one another. For example, if, as is usually possible, one edge or part of the kidney is observable, note whether the movement of this and the foreign body are coincident. If they move as one the inference is in favour of the object being a stone in the kidney, and if the relative movements do not coincide it is extremely probable that the contrary is the case. Contract the diaphragm upon this suspicious object and try to make out its outline. Renal stones have often such characteristic shapes that this may be valuable evidence. Systematic search is made in this manner in renal, ureteric, and bladder regions, being careful to look up as high as the last two ribs, and while in this position make the patient breathe deeply, for I have several times in this manner driven a stone from its lurking place behind a rib. The kidney is a more moveable organ than is usually described and normally moves appreciably with respiration. When examining over the bladder region pressure on the screen should be made as this much improves the screen picture. In this region the sacrum must be remembered, but its extreme symmetry prevents it being mistaken for calculus material; also, in the event of finding calculus in this region remember the possibility of its being in the lower ends of the ureters. I have found calculi in both ureters at the same time and from the comparison of their appearances have been able to give their composition; in one case this was oxalate of lime in the right and phosphatic material in the left. The photographic plate will be useful at this stage, for, having caught the calculus in as small a circle of light as is desirable for good definition, the plate in its light-tight envelope is placed over this spot between the patient and the screen—the rays being turned on and the lights in the room being out—a few seconds only are necessary by way of exposure with any good make of modern tube properly treated. There is no doubt that the diaphragm tends to increase the exposure, and this fact must be borne in mind.

Practice in viewing the abdomen with a fairly large diaphragm—say four inches—will reveal many of the organs there contained. It is always desirable to have the intestines as empty of solids and as full of gas as possible. In this condition the whole length of the colon is clearly and brightly outlined and as a contrast to the thick tissue of the kidney is most valuable, as it is usually easy to see the outer borders of these organs against the lighter colon. Scybala may lead to erroneous conclusions and I must confess to twice being the cause of unnecessary operations by the deceptive appearance of the renal area. This is not likely to occur again, for there is a way in which it may be avoided, and that is by examining the patients on two occasions, when the intestinal matter will, at any rate, have altered its appearance even if it has not completely passed away by suitable treatment. It is distinctly advisable, though not always feasible, that every case of suspected calculus should be examined twice if an operation is to be based upon the results of the x ray examination. Scybala more often lie to the outer side of the kidney and their presence then must make the operator suspicious of others possibly nearer the middle line. By observing relative movements, as the patient breathes deeply, mistakes may also be avoided.

I need not go further into the technique, the above description is a sufficient outline. In speaking of the screen in the diagnosis of urinary calculus I am not putting forward an untried theory, but one which a very large series of cases has proved to be sound and practical. It has reduced the inaccuracies of this branch of radiography to a minimum, and where failures do occur they are usually traceable to inability to carry out the method I have described completely. In the work I have done for St. Peter's Hospital and which, owing to the kindness of Mr. S. Allen, I have been able to check as to accuracy, there has not been an x ray report that has been proved incorrect since this system of strict screen examination was substituted for the former photographic method.

I would earnestly beg those who would avail themselves of the x rays in cases of calculus to insist, even in acute cases, that the screen be used, and this can be done without much inconvenience to the patient—indeed, with infinitely less than that occasioned by the old unsatisfactory system of pushing a plate under him and placing the tube above. It is no exaggeration to say that this plan will fail in two-thirds of the cases examined.

Harley-street, W.

A Medical Town Councillor.—Mr. H. F. Devis, L.R.C.P. Lond., M.R.C.S. Eng., was on Sept. 3rd returned at the head of the poll for the Somerset ward of the Bristol city council.

SOME OBSERVATIONS ON CONVULSIONS IN CHILDREN AND THEIR RELATION TO EPILEPSY.

BY R. O. MOON, M.D. OXON., M.R.C.P. LOND.,
PHYSICIAN TO THE WESTERN GENERAL DISPENSARY, MARYLEBONE, AND TO THE HOSPITAL FOR DISEASES OF THE HEART, SOHO-SQUARE, ETC.

THE great frequency of convulsions in children is a matter of common observation and as in other things familiarity breeds contempt, so here they are apt to be treated as of slight importance if gross lesions of the brain or toxæmic conditions such as uræmia can be excluded. While the immediate danger to a child from a convulsion may be slight and seem indeed to interfere but little with his ordinary health, the prognostic significance of such a symptom as to the future welfare of the child, especially his mental and moral condition, is far from being unimportant. Some time ago in these columns[1] I analysed the results of an investigation into a hundred cases of convulsions in children with a view to determine their relation to epilepsy and I now propose to examine a second hundred, many of which I have been able to observe owing to the kindness of Dr. F. J. Poynton who has allowed me to make use of some of the cases in his out-patient department at the Hospital for Sick Children, Great Ormond-street.

As in my former set of cases so in these I have not been able to find any clear dividing line between infantile convulsions or eclampsia on the one hand and idiopathic epilepsy on the other, nor could one say with Russell Reynolds that there is a sharp distinction between the two, that in fact "epilepsy should be regarded as an idiopathic disease, i.e. a morbus *per se*, which is to be distinguished from eccentric convulsions." On the contrary, it has seemed to me that convulsions in early life may shade off indefinitely into epilepsy or epileptiform manifestations, so that it becomes often impossible to say where the one stops and the other begins. Infantile convulsions do not, of course, necessarily pass on into epilepsy, but it certainly seems that a much larger number do so than is generally supposed and also that we have at present no adequate criteria for deciding in a given case in favour of the more or the less serious prognosis.

Etiology.—As in the previous series so here I have found in about half the cases that the first convulsion has arisen suddenly without any obvious cause, while the child has been in apparently good health, and it is to this kind of case that the name of idiopathic epilepsy is given; in the remainder the first convulsion has arisen in connexion with some extrinsic cause, such as teething, rickets, traumatism, specific fevers, indigestion, or indefinite conditions of ill-health. Among these reflex causes of convulsions rickets and teething stand out as certainly the most prominent, the former being responsible for 10 per cent. of the cases and the latter for 17 per cent.; in the former series this relationship also obtained. As to the association with specific fevers, one finds it difficult to believe that the occurrence is so frequent as text-books would seem to suggest. One can hardly believe that many observers would endorse the statement of Koplik[2] that "the majority of the convulsive seizures of infancy and childhood occur in connexion with the infectious diseases and at the onset of those affections." In my cases there were only three instances, two occurring prior to the onset of pneumonia and one in the course of pertussis. Speaking generally, it would seem to be true that in a child subject to fits the occurrence of a specific fever increases their frequency, and I would emphasise the fact that the same is true of adults when attacked by influenza. Still there are striking exceptions to this rule. Thus, a child who had been having convulsions about once a fortnight for six months was attacked by measles and then pertussis, during which time she had no fits and in fact remained free from them for six years. Another child who began to have fits for the first time at the age of six years with considerable frequency had in the preceding two years suffered from measles, scarlet fever, and pertussis without having had any epileptiform manifestation, which one might have expected to occur in such a case if the specific fevers were powerful agents in giving rise to convulsions. Heredity has been an important antecedent in 29 per cent. of the cases but the striking fact appears that a larger number of cases arising in association with reflex conditions owned a history of heredity than did those of idiopathic epilepsy.

Alcoholism.—A history of this was found in one or both parents in 10 per cent. of the patients and these were equally divided between both types of cases.

Prognosis.—Natural as it seems to suppose that the prognosis would be greatly better in cases originating in connexion with some peripheral irritation, where at all events there appears to be a chance of removing the cause, I have not found this borne out by facts. Thus of 50 cases of convulsions associated at their onset with some extrinsic cause such as I have enumerated above, in 40 per cent. the convulsions ceased after the removal of the apparent cause, while in 36 per cent. they continued; among the 50 cases arising from no apparent extrinsic cause, in 30 per cent. of cases they ceased while in 44 per cent. they continued. True, this shows a balance in favour of a more hopeful prognosis in the case of reflex convulsions, but the scale does not incline so heavily to that side as is usually supposed. The frequency of the fits is not, however, the most important matter in the prognosis. Epilepsy would not be so serious a disease if it were only the fits as such which had to be considered; unfortunately it is the mental and moral impairment of the patient which make the disease so universally dreaded. With regard to the question of mental impairment, we find that among those whose convulsions arose without any obvious cause 18 per cent. showed definite signs of mental weakness, while of those arising from reflex causes 23 per cent. suffered in this way. According to Savage "all epilepsy tends naturally to weak-mindedness, this depending rather upon the frequency of the fits than upon their severity, and epilepsy when occurring before seven years of age is certain to leave the patient weak-minded." We have not found the prognosis quite so bad as this, but doubtless had we been able to follow up cases much beyond the age of childhood we should have found a still larger percentage of cases that had been mentally weakened. Coming to the question of moral impairment, we again find a somewhat larger proportion of the cases due to reflex causes exhibiting moral deterioration than of the idiopathic cases; of the latter there were 34 per cent. and of the former 43 per cent. It is curious to note that a larger number of the children are affected prejudicially as to their general temper and character—that is, on the moral side—than as to their intellectual powers. Somewhat similarly it has been observed that in general paralysis of the insane it is the finer attributes of temper and character which begin to be blunted before the mental powers show definite impairment; possibly the former are flowers of more delicate growth so that very slight disturbances cause them to wither. Even after all convulsions and *petit mal* attacks have definitely ceased we often find manifestations of nervous instability which, though not epileptic, seem to have some affinity with epilepsy and might be called, to use Spratling's expression, "fragments of epilepsy."[3] Thus two of my cases after the cessation of convulsions suffered from enuresis, and a third from night terrors; in these the initial convulsions had occurred in connexion with rickets. We have similar instances in the case of those whose first fit was associated with teething. One patient after the cessation of the fits used to suffer periodically from a peculiar knocking sensation at the forehead, while another had occasionally temporary paresis of the right arm and leg, a third suffered from somnambulism, and in a fourth asthma occurred. Instances such as these seem to indicate that a radical unsoundness of the central nervous system is a more important factor in the production of infantile convulsions than an extrinsic cause.

Treatment.—I have little to add to my previous observations on this head. Urethane was tried in a few cases where other drugs had failed, and in three instances it certainly did good and I have not found that it has had any prejudicial effect on the general health. Spratling speaks of it as worthy of trial in cases in which the bromides give no benefit. Chloral is often useful as a temporary measure when the fits are very frequent and violent, but it is important to leave it off gradually, as when stopped abruptly it seems to make the child peculiarly restless and irritable. As to surgical operations, one case became distinctly worse after the removal of tonsils and adenoids, another was unaffected in any way by the same operation, while a third seemed to improve. One case suffering from rather bad phimosis showed no improvement as regards the convulsions after being circumcised.

Conclusion.—From what has been said it seems difficult to avoid the belief that convulsions in infancy associated with reflex causes have a much more serious prognostic signification than is usually supposed, not only as regards the frequency of the convulsions but still more as to the probability of future mental and moral deterioration. The reason why it has been customary to attach so much importance to convulsions of idiopathic origin is twofold: (1) the great *a priori* probability of such a view, and (2) the failure to follow up for any considerable length of time cases of convulsions associated with reflex causes. It is only the latter more humble task which I have been attempting here: at the same time, one might point out that the *a priori* reason is not so formidable as it seems. "Cessante causa, cessat et effectus" sounds very conclusive, but, of course, when we speak of rickets, teething, specific fevers, &c., being reflex causes, in strictness of logic they are merely antecedent (or concomitant) conditions, the cause being simply the totality of antecedents among which the intrinsic condition of the brain may possibly be the most important. One might also readily argue that a convulsion, to whatever cause it may be due, must have some effect upon the brain and that the nervous system very easily forms habits, so that the fact of having had one convulsion, however induced, renders it more liable to have another quite apart from any extrinsic cause. However this may be, the fact remains that in 200 cases taken haphazard, carefully investigated and followed up, the prognosis as to the future moral and mental condition of the child does not appear to be any better when the first fit is associated with a reflex cause which can be removed than when it is of idiopathic origin. It will, however, be necessary for our knowledge of the pathogenesis of epilepsy to be much further advanced than it is at present before its precise relationship to infantile convulsions can be determined.

Green-street, W.

THE PROPHYLACTIC USE OF ANTI-DIPHTHERITIC SERUM.

BY WILLIAM W. SHACKLETON, M.D. DUB.

THE following short account of the prophylactic use of anti-diphtheritic serum during an outbreak of diphtheria last autumn in a school containing over 300 boys may be of interest.

On Sept. 7th, 1905, two cases occurred in a junior house (which I will call E House) which had at the time 44 boys resident in it. From that time to the 13th four more cases occurred in this house and one in a senior house. In addition to these a boy in E house was removed and isolated on account of having a nasal discharge in which Klebs-Löffler bacillus was found; this boy was placed amongst the diphtheria cases and by douching a quantity of the membrane was removed from the nasal cavity. Out of 45 boys seven had developed diphtheria. I therefore on the 13th inoculated all the boys remaining (38) in House E with 2000 units of anti-diphtheritic serum supplied by Burroughs and Wellcome. The next morning (the 14th) one case occurred and after that not a single case occurred for five weeks in this house. I examined these boys' throats every day and took swabs therefrom. I found nine boys with the diphtheria bacillus present. These boys I isolated (not putting them, however, with the diphtheria cases) and kept them so until swabs were obtained free from the bacillus. The bacilli were persistently present in one boy's throat for five weeks, at the end of which period he developed small patches of membrane on each tonsil. He had been inoculated on the 13th with his house. This is interesting as tending to support the view generally held that the prophylactic effect of the serum lasts about five weeks.

On the 28th I saw a boy from a senior house who had well-marked membrane on the tonsils and soft palate. The diphtheria bacillus afterwards was proved to be present. He acknowledged that he had had a sore-throat for two or three days but had kept the fact to himself. I therefore examined all the school (317) and found two cases of diphtheria. On the following day, with the help of my colleague, Mr. G. Francis Smith, and Dr. J. H. Hebb, all the boys in the school (with the exception of E house previously done) were inoculated with 1000 units of anti-diphtheritic serum supplied by the Lister Institute. No more cases occurred amongst the senior boys.

In E house, which was the original focus of infection, one case occurred on Oct. 18th. This case was that of a boy who had come back on Oct. 14th and was not inoculated. He was the only boy in the whole school (except those who had actually developed diphtheria previously to the inoculations) who had not had a prophylactic dose of serum. Amongst the 317 healthy boys inoculated no ill effects ensued. One boy was kept in bed two days as there was a good deal of pain and swelling in the region of the inoculation. No other boy was absent from the school or unable to play games. Many had slight urticarial rashes. I found that the least painful place to inject was the buttocks. The inoculation of this large number of boys was done in about two and a half hours, thanks to the able assistance of the staff. All that we had to do was to fill the syringes and inject. By having a good supply of needles a sterilised needle was always ready. The skin was previously well scrubbed with soap and antiseptic and covered with a moist dressing, gauze being strapped on immediately after the injection. On the 19th the boys of E house were for a second time inoculated with 1000 units of serum. This I did after the boy who had missed being inoculated developed diphtheria. A month had elapsed since the first inoculation.

To sum up. No case occurred amongst boys belonging to E house after the first inoculation for five weeks, except one, and that on the day following the injection. The case that did occur at the end of five weeks had the Klebs-Löffler bacillus present during the whole of that period. One other case occurred in E house but that was in the case of the only boy who had not received any serum. No case occurred amongst the senior boys after the injection, although three cases had occurred and these were freely mixing with their companions until detected and removed. That no cases did occur and escape detection I am pretty certain, as I made a daily inspection of all the boys' throats for a considerable time. I may add that all the 14 cases of diphtheria did well. With the one exception of the boy at large for two or three days all of them got inoculated within a few hours after the first symptoms of the disease had manifested themselves.

A CASE OF FAUCIAL ANGINA WITH FALSE MEMBRANE (NON-DIPHTHERITIC) SIMULATING DIPHTHERIA.

BY J. T. C. NASH, M.D. EDIN., D.P.H. CANTAB.,
MEDICAL OFFICER OF HEALTH OF SOUTHEND-ON-SEA; MEDICAL SUPERINTENDENT OF SOUTHEND-ON-SEA BOROUGH SANATORIUM.

A WOMAN, aged 38 years, felt her throat uncomfortable on August 5th, 1906 She sought advice on the 6th, when the pharynx was found to be slightly congested and a thin film was observed on the tonsils which, however, were not noticeably enlarged. There was no nasal discharge nor were any glands unduly enlarged. The film on the tonsils was easily removeable without leaving a bleeding surface These early clinical signs were on the whole against a diagnosis of diphtheria. Cultivations made from a swab showed the presence of cocci and a few wedge-shaped bacilli. On the 7th there was a more pronounced film, a second swab cultivation showing streptcocci and other cocci. On the 9th there was definite false membrane of considerable extent and thickness. Large patches were visible on the left tonsil and behind the posterior pillar of the right fauces. A piece of membrane stained and examined for bacteria showed the presence of streptococci and other bacteria. A swab cultivation after 24 hours' incubation showed the presence of spirilla, large fusiform bacilli, small faintly stained bacilli, a few tetracocci, and streptococci. The combined clinical and bacteriological evidence at this date appeared to indicate a case of Vincent's angina. In view, however, of the definite typical false membrane diphtheria antitoxin (2000 units) was administered. Pure lysol and undiluted tincture of iodine B.P. were applied to the patches and a mixture of the perchlorides of iron and mercury was administered. On the 16th the following note was made: "Membranous formation still continues. The subjacent tissue, which at first was merely congested, has later become ulcerated and bleeding occurs on removal of the false membrane." A further swab cultivation showed numerous long streptococci but no diphtheria bacilli. From this date onward improvement gradually set in, the membranous formation (which was removed two or three times a day) becoming thinner, until finally it appeared to be nothing but the exudation from healing granulations.

Apart from the very definite false membrane of considerable extent the clinical signs were in my opinion against a diagnosis of diphtheria. This opinion was sustained by no fewer than five or six carefully made *negative* swab cultivations and by the clinical course of the case. The temperature *did not at any time fall below normal.* The case emphasises the importance of bacteriological confirmation of a provisional diagnosis of diphtheria, if such diagnosis is based on membranous formation alone. It further emphasises the importance of reserving an opinion until all the evidence available has been obtained. The reservation of diagnosis should, however, not interfere with the prompt administration of a small dose of diphtheria antitoxin, which should be administered without delay *in every* doubtful case without waiting for bacteriological evidence. It is unnecessary, I hope, to add that all necessary precautions were taken in the way of isolation and antiseptic applications throughout the case, for even if not a case of diphtheria such a throat is probably of an infective nature. Amongst precautionary measures for the prevention of spread in cases of infectious diseases, in addition to the efficient isolation of the patient I always advise the daily methodical use of an antiseptic gargle (preferably a solution of permanganate of potash) on the part of others living in the same house or who have otherwise been exposed to infection.

As to the etiology of the above case there was a history of dust having been blown into the mouth a day or two before onset. This dust probably carried in deleterious bacteria, such as streptococci, &c. The organisms cultivated from the false membrane were probably saprophytic bacteria which had found a suitable nidus for development in the false membrane. An important diagnostic point is the course of the temperature. In true diphtheria this soon becomes, and for a long time remains, subnormal. In the present case the temperature was never subnormal.

Southend-on-Sea.

FRACTURE OF THE EXTERNAL CONDYLE OF THE HUMERUS.

BY W. E. HOME, M.D. EDIN.,

FLEET SURGEON, R.N.

FRACTURE of the external condyle of the humerus is so uncommon an accident that it may be well to put a case on record.

On July 23th a stoker on H.M.S. *Exmouth* caught his right elbow under the cross-head of a hydraulic engine. So violent was the blow that his arm bent the rim of a cast-brass lubricating cup. On examination he was found to have a lacerated wound on each side of the elbow. From the inner wound the finger passed through lacerated tissues down to the front of the humerus. Within the outer wound the muscles were slightly lacerated, the skin was partially separated even where not ruptured, and about an inch of the external condyle and supracondylar ridge was found lying free. No arteries bled. The loose piece of bone was fixed by a suture through its adherent soft parts. The wounds were drained and sutured (one deep silkworm-gut suture of relaxation, the others catgut continuous), and the elbow was put up in cotton wadding with elastic bandage over all. The drain was removed from the inner wound on the second and from the outer on the third day. The after-history was uneventful. The wound is now under cyanide gauze and collodion.

H.M.S. *Exmouth.*

Reviews and Notices of Books.

Traité d'Hygiène. Publié en fascicules sous la direction de M BROUARDEL et M. MOSNY. *Hygiène Navale* Par les Drs. DUCHATEAU, JAN, et PLANTÉ. (*A Treatise on Hygiene*, published in parts under the direction of M. BROUARDEL and M MOSNY.—Part 10, *Naval Hygiene*, by Dr. DUCHATEAU Dr. JAN, and Dr PLANTÉ.) One volume in octavo. 356 pages, with 36 illustrations in the text and three coloured plates. Paris: J. B Baillière and Son. Price 7 francs 50 centimes or in boards 9 francs.

IN this great work on hygiene the aim of the editors, the late Professor P. Brouardel and Dr. E. Mosny, is to formulate the contemporary hygienic knowledge of the world in as complete and perfect a manner as possible. It would be difficult to find two men better equipped for the task. Their names alone are an ample guarantee for the thoroughness of the work but they have, moreover, been successful in securing the collaboration of such well-known authorities as M. Chantemesse, M. Netter, M. Widal, M. Wurtz, M Dupré, M. Thoinot, and M. Courtois-Suffit of the Faculty of Paris; M. Courmont and M. Lesieur of Lyons; M. Rouget and M Dopter of Val-de Grâce; M. de Launay and M. Leclerc de Poligny, engineers; M. Ogier; M. Bonjean; M. L. Martin, chief medical officer of the Pasteur Institute; M. Calmette, director of the Pasteur Institute at Lille; and M. A. J. Martin, inspector of Parisian sanitation. It is proposed to complete the work in 20 parts, and so far five parts have been published dealing respectively with Atmosphere and Climate, Soil and Water, Individual Hygiene, Alimentary Hygiene, and Naval Hygiene. The last-named fascicule, as it is termed, which has just been submitted to us for review, stands tenth on the list and is divided into two sections. The authors of the first section, which treats of the navy and occupies about two-thirds of the volume, are Dr. Jan and Dr. Planté, both senior officers on the active list. For the second section, which occupies the remaining third and is devoted to the mercantile marine, Dr. A. Duchateau, who like his colleagues belongs to the navy, is responsible.

The French navy, in common with the other first-class navies of the world, has undergone such a complete transformation during the last few years, not only as regards ironclads and cruisers but also in connexion with the still progressive development of torpedo vessels and submarines, that the best attention has been devoted to attending to the sanitary details of the new constructions. No war vessel is now projected in which the requirements of hygiene can be said to be unduly disregarded. Of course, everything must yield to expediency. A war vessel is not a pleasure yacht; before everything it must be as good a fighting machine as possible; but in many ways that formerly were overlooked the health, and consequently the efficiency, of the fighters can now be safeguarded without interfering with power. From the point of view of the pure combatant hygiene should by no means be a negligible quantity. In the first subsection of their section Dr. Jan and Dr. Planté deal with war vessels; the internal arrangements of the several types, their habitableness, ventilation, warming, lighting, and water distribution. In the second subsection the mode of life of a modern sailor belonging to the navy is exhaustively reviewed as regards recruitment, duty, general and personal hygiene, and food. The third subsection treats of pathology and prophylaxis in peace time as well as during war. In their fourth and last subsection the authors have to do with barracks and hospitals on land, together with the hygiene of arsenals and workshops. Under all these various headings we obtain instruction and information from men who write with full knowledge of their subject.

Dr. Duchateau commences his section with a disquisition on the rules and regulations affecting life and health which are common to all vessels engaged in commerce, including passenger traffic. Of late years something has been done to improve the hygienic condition of the mercantile marine, but many and grave defects still need remedying, especially in vessels of low tonnage which are destitute of medical supervision. The subject bristles with difficulties, chiefly on account of the opposition of small owners. On the great liners the needs of the crew are fairly well attended to, but in "tramps" the men are often treated like cattle. It is easy for a government to issue ordinances but their enforcement is not easy. Prejudice and routine together are too strong for the average legislator whose well-meant efforts consequently remain a dead letter. Dr. Duchateau affords complete details regarding the recruitment, composition, and strength of crews in French mercantile vessels, and discusses the employment of native assistance in Oriental waters. Then he turns to the hygiene of the different classes of vessel, including yachts, which are engaged in commerce, paying special attention to the fishing fleets which frequent the Northern seas. Chapters on ships and their cargoes and benevolent institutions follow, and the section concludes with an *exposé* of the diseases and accidents to which men who go down to the sea in ships and do business in great waters are peculiarly liable.

We are accustomed in England to receive our books with the pages cut ready for reading, but this praiseworthy concession has not as yet taken root in France. This is the only adverse criticism which we have to offer upon a thoroughly interesting and suggestive work.

Thought Transference. A Critical and Historical Review of the Evidence for Telepathy, with a Record of New Experiments, 1902-1903. By NORTHCOTE W. THOMAS, M.A. 1905. Pp. 214. Price 3*s.* 6*d.* net.

Crystal Gazing: Its History and Practice, with a Discussion of the Evidence for Telepathic Scrying. By NORTHCOTE W. THOMAS, M.A. With an introduction by ANDREW LANG, M.A., LL.D. 1905. London: Alexander Moring, the De la More Press. Pp. xlvii. + 162. Price 3*s.* 6*d.* net.

THE first of these two volumes is devoted to an examination of the evidence of thought transference. The author has examined the records of the Society for Psychical Research, together with other recorded examples, with a view to establishing the necessary criteria for belief in such a phenomenon. It is obvious that the difficulties to be encountered in any such investigation must be enormous, and that the details of any reputed success require the most rigorous analysis in order to eliminate all possible sources of fallacy. Mr. Thomas points out the importance of telepathy as a fundamental conception in regard to psychical research, defining it as an "influence of mind on mind exerted through other than the ordinary channels of the senses." He refers to the very numerous sources of error to which experiments in this direction are liable, among them being hyperæsthesia of the special senses, "subconscious interpretations of subconsciously perceived indications," where the subject and agent are within sight of one another, and "muscle reading," which entirely vitiates the validity of any experiment where contact is permitted. The importance of the subliminal consciousness in reference to telepathy is the subject of one chapter and the author states that "there is reason to suppose that the *primâ facie* telepathic impressions, the impressions communicated by other means than ordinary sensory methods, depend for their communication in some way on the subliminal consciousness." The reasons for this statement, however, are not given, indeed in the next sentence we are told that "how this happens we cannot, of course, say." This is the more to be regretted in that Mr. Thomas in one of his earlier strictures on incredulity specifically excepts the "sane scepticism which refuses to accept statements not backed up by sufficient evidence." The book contains a brief history of some of the experiments which have been made by various observers. The occurrence of telepathic hallucinations, telepathic hypnotism, and telepathic dreams is discussed and reputed examples are quoted. Then a record is given of some experiments conducted in 1902, mainly under the supervision of the author. In these experiments pictures, colours, diagrams, and numbers were suggested to, or given to, one party to the experiment called "the agent"; another called "the percipient," recorded the impressions received, the two being unable to communicate directly with one another as they were separated by a double screen. The supervisor of the experiment was so placed as to be able to watch both "agent" and "percipient." The net result of all the experiments is discussed, but the author leaves his readers to make up their own minds, merely hinting his own conviction that much more effort is needed before it can be maintained that telepathy is an established fact. Here Mr. Thomas is most temperate in his conclusions and in his recommendations, but at times he is intemperate in his criticism of those who are incredulous of the results of what is called psychical research, notably in his scorn of the psychologist and of the modern school of experimental psychologists who are endeavouring to apply mathematical and experimental methods to the elucidation of mental processes. We ourselves come under the lash of his satire for a criticism of certain recorded experiments.[1]

The other volume by the same author is devoted to a study of crystal gazing. It begins with an introduction by Mr. Andrew Lang, who affirms his belief in the capacity which some people are said to possess of observing people, places, or incidents, or "scrying" as it is called, in crystal globes, giving instances which have come under his own observation, where the element of possible fraud was reduced to a minimum. Mr. Thomas tells us that a crystal vision is simply a day-dream and that the faculty of "scrying" is closely allied to that of visualising. He gives an interesting history of crystal gazing and of the allied conditions of gazing at polished sufaces, or at water, at ink, or at the viscera of slain animals, as in the divinations of ancient times. We must confess that even after reading Mr. Thomas's book we do not regard crystal gazing as likely to be fruitful of much advance in useful knowledge. These two little volumes are obviously written with a view to provide some general information on the subjects dealt with so as to render "both scepticism and credulity less excusable"—as the author says in his preface. There can be no doubt that the deceptions and frauds of plausible rogues, to which workers in the field of psychical research are from the nature of things peculiarly liable, have done much to bring that form of investigation into disrepute, especially among the workers in physical and morphological subjects, where the conditions of experiment are more easily definable and where exact methods are more readily applicable. The author has endeavoured, and with no small measure of success, to indicate that there is a field for research and that very little has so far been accomplished. He is perhaps too severe on the incredulous and the sceptical, and too prone to regard recrimination as argument, for he should remember that the onus of proof lies with those who affirm the existence of these phenomena, and with them likewise lies the refutation of adverse criticism, not in a spirit of irritation, but by actual demonstration of the errors of that criticism.

---

[1] THE LANCET, May 21st, 1904, p. 1431.

A System of Surgical Nursing, with an Appendix containing Useful Formulæ, Emergency Drill, &c. By A. N. MCGREGOR, M.D. Glasg., F.F.P.S. Glasg., Assistant Surgeon to the Glasgow Royal-Infirmary. Glasgow: David Bryce and Son. Pp. 554. Price 9*s.* net.

How much should a nurse be taught of general and special surgery? The answers of this question differ widely, if we may judge by the books provided for the teaching of surgery to nurses. The work before us is one of the best of its class, and its only real fault is that it supplies much more knowledge than the average nurse will ever absorb. There are in all 42 chapters without counting the appendix. The titles will sufficiently indicate their contents: General Principles of Surgical Treatment; Sepsis and Asepsis; Bacteria; Antiseptics; Wounds; Hæmorrhage; Treatment of Hæmorrhage; Repair of Wounds; and so on. Diseases are considered as they affect the various systems, the digestive, the nervous, and bones and joints. We have said above that we consider the book very good of its kind, though it may be a little over the head of many nurses. The teaching is good, and many useful hints are given on points which should be known to all fully trained nurses. There are no illustrations, not even in the chapter on bandaging, but we think that illustrations would have enhanced the value of the book in many of the chapters. We have little to say in criticism of individual statements. Saline solution is said to be of the strength of 0·6 per cent. It is generally recognised now that a somewhat higher percentage is preferable as more isotonic with the tissues. Saline solution, we are told, is only feebly bactericidal; we should be glad to have proof that it is bactericidal at all. The book is well printed on stout paper and it should prove very useful to any surgical nurse desirous of carrying out her duties intelligently and efficiently. We regret to see that the book is undated.

LIBRARY TABLE.

The Science of Common Life. By JOHN B. COPPOCK, B.Sc. Lond., F.I.C., F.C.S. With 76 illustrations. London: Swan Sonnenschein and Co., Limited. 1906. Pp. 273. Price 3*s.* 6*d.*—The science of common life cannot, of course, be summed up in a scheme of experimental chemistry and physics, which are after all the subject matter of this book. Nevertheless, the things of common daily contact are in the main evidences of chemical composition, activity, and affinity, and the presentation of these facts in scientific, yet withal intelligible, terms is the task which Mr. Coppock has undertaken, and, we may add, undertaken well. Primarily the book has been written to meet the requirements of the Board of Education's Syllabus on "The Science of Common Life," but we are glad to note that the author repudiates the common charge brought against cram-book writers, that their works are written strictly within the confines of a syllabus and therefore are opposed to true educational methods. He purposely omits, for example, to summarise the facts at the end of the chapter: "The student is asked to draw up his own summary after assimilation of the contents of a chapter. The summary provided by a master for a student without the student's previous assimilation of the material is not real knowledge but 'cram'—in short, not educational." We commend this opinion thoroughly. The chemistry and physics of common daily facts are set forth throughout the book in terms which should be intelligible even to the general reader, who may be undisturbed by thoughts of, or preparation for, an impending examination.

A Laboratory Manual of Physiological Chemistry. By ELBERT W. ROCKWOOD, M.D., Ph.D., Professor of Chemistry and Toxicology and head of the Department of Chemistry in the University of Iowa. Second edition. Revised and enlarged. Philadelphia: F. A. Davis Company. 1906. Pp. 229. Price $1.00 net.—This book provides an excellent laboratory course of physiological study and evident pains have been taken to bring the subject matter into accord with recent advance. We have followed the detailed directions given in the experimental portions of the book, and the conclusion is inevitable that the writer is perfectly familiar with those experimental details which are essential to success. There is, however, a tendency throughout the book to bring into prominence some experiments and to undervalue the importance of others, a course which suggests a routine for mere examinational purposes. The author, indeed, says that "for the purpose of making the course flexible the less important experiments or those which are not of general interest have been printed in smaller type." We cannot agree always that the matter in smaller type is of less importance; for example, the tests for albumin in urine and the fallacies of the tests for sugar in urine are of the first interest. By the way, is it not a little inconsistent to write "chlorin" and "iodin" while the French word "gramme" is retained in the unabbreviated form?

Looking Back.

FROM

THE LANCET, SATURDAY, Sept. 13th, 1828.

RUSSIAN ARMY AND NAVY MEDICAL SERVICE.

To the Editor of THE LANCET.

SIR,—Many English surgeons having proceeded to this place, in consequence of the official notification which has been addressed to foreign medical men, you will be doing a great piece of justice to the medical men in England, if you will have the goodness to communicate to them, through the medium of your valuable Publication, the contents of this letter, which may serve to give some idea of the treatment *they* will experience on coming to Russia. In the first instance, the notification states, they may either join the land or sea service. This is false; for on the application of *Englishmen* who have just arrived here, they have been told "the army is fully supplied;" and they may either embrace naval service, or return to whence they came. In the next instance, as regards the examination at the Academy, there are at present not less than thirty young men, principally Germans, with the exception of three Englishmen, who came to Petersburg with the idea of entering the service, according to the notification, who have been in attendance on the learned professor at the Academy for the space of *three months*, and with every probability of remaining three months longer. The conduct observed towards them has been highly infamous, and the state they are now in to my certain knowledge, is truly deplorable; in fact, nothing remains to be done but their immediate application to the different consuls or ambassadors, to be sent home as distressed subjects. Yesterday a body of them presented petitions to Dr. Cardanoff (the president of the Academy, in the absence of Sir James Wylee), for the return of their different certificates, preferring to get back as they can, to remaining in a country where they have been treated more like dogs than Christians. By making this publicly known, you will be doing much service to those gentlemen who have any idea of proceeding here.

I remain, Mr. Editor,
Your obedient Servant,

St. Petersburg, July 8, 1828. HENRY WILLIAMS, M.D.

THE BRITISH MEDICAL ASSOCIATION.

MEETING AT TORONTO.

(FROM OUR SPECIAL CORRESPONDENTS.)

THE Congress of the British Medical Association at Toronto closed on Friday afternoon, August 24th. The estimate of the numbers at the meeting already sent to you—viz., 2200—turned out to be practically correct, and it is generally considered that this constituted a very remarkable attendance.

The 13 sections were all located in the University and its constituent buildings and colleges, and were indicated by various sign-posts directing the way. The university park covers a considerable extent of ground, so that although all the sections were within its precincts they were not under one roof. A very useful addition to each section was a special room for the officers of the section. Most of the sections attracted considerable numbers to their meetings, and the discussions were of a high order of scientific and practical value, while the joint discussions held by various sections proved to be of great assistance and interest. The convenient manner in which the sections were housed, as well as the preliminary committee meetings held at the beginning of the week, much facilitated all the business of the sections.

The weather during the meeting has been extremely hot, and the great humidity of the atmosphere has made it uncomfortable for English visitors. But the two sharp thunderstorms which occurred during the week, associated with an almost tropical deluge of rain, had the effect of lowering the temperature, and apart from them the weather has been bright and clear. A topic of general discussion has been the general ignorance of the English people of the extent of Canada and of the nature of its climate. No little amusement has been caused by a report which is current that certain specimens sent to the exhibition were labeled, "Protect from frost."

The church service usually held at the commencement of the meeting was this year omitted, it will be perceived, but the proceedings of the inaugural ceremony were opened with prayer.

With regard to the social entertainments provided for the members, visitors, and ladies accompanying them, these have been unusually numerous and have been carried out with that open-handed generosity characteristic of the Canadians. Luncheon parties, garden parties, and evening receptions were given on each of the days of meeting. Among the parties, in addition to those already noticed, may be mentioned a luncheon for visiting ladies at the Lambton Golf Club on Wednesday, and garden parties given by Mr. and Mrs. Cox, and Mr. E. B. Osler, M.P., and Mrs. Osler. An evening reception was held on Wednesday by the Mayor and the City Council at the City Hall; on Thursday there was a reception in the Dean's garden at the University, and on Friday a very pleasant *réunion* was organised by the Royal Canadian Yacht Club at their club house on Toronto Island.

The excursions commenced on Saturday. The Entertainment Committee had arranged some attractive excursions, among them one to the Muskoka lakes and another to Niagara. The party for Niagara left Toronto at 9 A.M. and were taken to the Niagara Power Company works, now in course of construction, and afterwards entertained to luncheon at the Clifton Hotel by Sir Henry M. Pellatt. The enormous turbines now being installed and the long tunnel through which the water will be discharged afforded a most interesting and instructive sight. After luncheon the party made a tour of the Falls and of the Niagara River Gorge, *viâ* Queenston, Lewiston, and Niagara Falls, N.Y., returning to Toronto in the evening.

A considerable number of the British visitors left Toronto on Friday by the Canadian Pacific Railway to make the journey across the Rocky Mountains to the Pacific coast at Vancouver, which affords an excellent opportunity for observing the great resources and the wonderful scenery of the Dominion. Special facilities have been offered by the Canadian Pacific Railway Company to members attending the meeting, and many are availing themselves of the opportunity to remove some of that ignorance upon which Lieutenant-Governor Mortimer Clark expressed himself so strongly.

In preparing our reports of the proceedings at the general meetings and meetings of sections which follow we have received the most unvarying assistance from all the officials of the British Medical Association, and we wish to repeat our acknowledgments to them.

THE GENERAL MEETINGS.

TUESDAY, AUGUST 21ST.

THE first annual general meeting was held in the Convocation Hall on August 21st at 2 P.M. The Convocation Hall is a new building not yet entirely completed. It is of octagonal shape and is of classic design, its front elevation recalling that of the Pantheon at Rome. The chair was taken by the President, Mr. GEORGE COOPER FRANKLIN, of Leicester. In a brief speech Mr. Franklin said that it was his duty and privilege as *laudator temporis acti* to refer to the past year's work of the Association. He alluded to the time, work, and devotion given to it by gentlemen in busy practice who became members of council, representatives and members of committees. During the past year the rebuilding of the office at 429, Strand had been decided upon. He thought the Medico-Political and Ethical Committee deserved all the praise that could be bestowed on it. He wished to express his gratitude to the officials of the Association for their help during his year of office, mentioning especially Mr. Guy Elliston, Mr. Smith Whitaker, and Dr. Dawson Williams. He then introduced the new President, Dr. R. A. Reeve, dean of the University of Toronto, who took the chair and was presented with his badge of office by Dr. F. N. G. Starr, one of the local honorary secretaries. The delegates from British and colonial branches and the distinguished visitors were then presented to the new President. The former were numerous and came from nearly all the English, Scottish, and Irish universities and colleges and from many of the colonies, including all parts of Canada, Nova Scotia, India, Australia, New Zealand, and South Africa. Among the American delegates were Dr. W. J. Mayo (Rochester, New York), President of the American Medical Association, Dr. G. Ross (Richmond, Virginia), Dr. A. Macdonald (New York), and Dr. R. Woodward of the United States Department of Public Health and Marine Service. The foreign delegates included Professor Aschoff (Freiburg), Professor Delsaux (Brussels), Dr. Delezenne, Dr. L. Lapicque, Dr. Nicloux, and Dr. Nicolle of Paris, and Professor Gaule of Zürich. The MAYOR OF TORONTO then extended the welcome of the city and corporate council to Toronto, "the queen city of the west." They were delighted to welcome the Association and would do all in their power to render the visit a pleasant one. Professor IRVING H. CAMERON delivered a short address of welcome on behalf of the local reception committee, while Professor ALEXANDER MCPHEDRAN and Dr. G. A. BINGHAM delivered similar addresses on behalf of the Canadian Medical Association and of the Ontario Medical Association respectively. In accordance with the usual custom Mr. Franklin, the retiring President, and Sir Victor Horsley were elected Vice-Presidents of the Association for life. Dr. REEVE then delivered his presidential address, in which he reviewed some of the chief advances made in medicine and its attendant sciences during the past decade.

The Presidential Address.

The PRESIDENT at the commencement of his inaugural address expressed his thanks for the position of honour in which he was placed and then made some reference to the success which had attended the meeting of the Association held at Montreal in 1897. He claimed that the credit for the auspicious conditions under which this second visit of the British Medical Association to Canada was made must rest largely upon those who had freely given most valuable help in various ways. It had been indeed a labour of love to bring the select and the elect of the profession from their posts of duty and busy round in the old homeland. He greeted them not only for their own sakes as men whose names were already household words or doubtless soon would be, but as worthy sons of worthy sires. For if Bacon, Shakespeare, Newton, Faraday, Kelvin, Clerk Maxwell, J. J. Thomson, and other lights of literature, science, and philosophy in the British firmament, were blotted out there would only be a partial eclipse, for would not Hunter, Harvey, Sydenham, Jenner, Simpson, and Lister present a resplendent galaxy? He pointed out that the present gathering was almost a cosmopolitan one. International comity had always prevailed in the medical profession, for disease knew no distinction of country or race and was the common lot of humanity. In the face of a ubiquitous foe it was natural that the confraternity of the healing art should be undivided. The recognition of English talent and experience on the part of the late Emperor of Germany, the consideration shown by the British sovereign to the eminent bacteriologist Professor Robert Koch, and the action of the United States in calling to its counsels British experts in tropical medicine upon the threatened invasion of yellow fever, were convincing proofs of the international harmony which existed with regard to the prevention of disease. The Canadians, for their part, were glad in obedience to the unwritten code and by means of this gathering to aid in cementing the tie that already bound the great Anglo-Saxon people to those of the lands of professional culture and erudition—France and Germany.

The President then briefly sketched the early history and subsequent development of the British Medical Association. In the next place he reviewed the progress made in medicine during the last decade. Many years, he said, must be regarded as compressed into the decennium in which Lister and Pasteur, Koch, Metchnikoff and Behring, with genius and untiring energy in quest of truth, solved their mighty problems and gave the world such talismanic words as antisepsis, asepsis, immunity, and serum-therapy. The work of these men proved not only a vast boon to sufferers from accidents and disease but a grand object-lesson to mankind in general and recent years had seen the result in princely gifts bestowed in the interests of science and humanity. An immense amount, however, still remained to be done. It was true that nursing had become a fine art, diphtheria had been largely robbed of its terrors, and, though rampant, was curable, and the mortality of typhoid fever had been reduced one-half. On the other hand, however, the fatality of cancer had steadily increased; tuberculosis, which had been called the white plague, stalked through the land, and the death-rate of infants, owing mostly to intestinal troubles, although not on the increase, was still very high. One almost felt as if the hands of the clock had gone back on the dial of the world's progress when one recalled that at Jenner's centenary the city where his method of vaccination had come into vogue was in the throes of an epidemic of small-pox due to the ignoring of his great discovery. There was yet ample scope for State medicine to ply its persuasive powers until men thought aright about matters which affected the well-being of the community, and the presumed welfare of the individual was not allowed to stand against the weal of the masses. In the matter of compulsory vaccination a true paternalism of the State with the active support of the medical profession should override so-called conscientious scruples. When vaccination was performed under the rules of asepsis, as it always ought to be, and with the use of pure lymph now always to be had, the risk was practically nil. The work of the decade had given the profession itself some new ideas in regard to the mechanical and chemical processes of digestion. It had been shown that the first part of the stomach was a mere receptacle and that the second part was a kind of mill which was perforce the more common seat of mischief requiring surgical treatment. The value of thorough mastication and the necessity of the avoidance of mental states which would divert nervous energy and thereby interfere with the digestion had been shown by Pawlow's studies. A notable work on "Physiological Economy in Nutrition" by Professor Chittenden of Yale University embodied the basis of a change of faith and a new practice. Professor Chittenden had proved incontestably that too much food not only meant loss of vitality in the disposal of it but entailed a positive risk from the resulting toxins ere these products of metabolism were finally got rid of. He had also shown that one-half or one-third of the nitrogenous (protein) food ordinarily taken was sufficient for maintaining the bodily energies, and that this reduced dietary entailed a minimal tax upon the liver, the kidneys, and the digestive tract. A supply of clean pure milk to communities was declared to be one of the greatest boons to humanity and good service in keeping this question before the public had been done by the pædiatric societies in the United States. The warning of Sir Thomas Barlow in 1894 was quoted to the effect that condensed milk, and even sterilised milk, were not efficient substitutes for the natural food of the infant and that infantile scurvy might be caused by their sole use. The marked increase in the debt which medicine owed to physiology and physiological chemistry was acknowledged and a grateful tribute was paid to Sir Victor Horsley for his researches in physiology. With the growth of more exact knowledge of the causes and nature of disease there had come more faith in the natural powers of the human body and in the value of the aid which could be given by nursing, dieting, &c. The discovery that pneumonia was always a septicæmic disease and that its specific microbe was present in the blood gave the clue to its prevalence and high mortality—greater indeed, than of yore, doubtless owing to the large and increasing percentage of dwellers in cities and towns. A protective and curative serum or "vaccine," as in the case of diphtheria or typhoid fever, was the hoped-for remedy. The discovery of a specific microbe in cerebro-spinal meningitis, the recognition of its mode of entrance into the system through the mucous membrane of the nose and throat, and the trial of repeated lumbar punctures and injections of diphtheria antitoxin with uncertain results, were features of interest in this serious malady which, by the way, was not so fatal as some supposed. The discoveries that the infections of yellow fever and malaria were carried by flies were reviewed and tributes were paid to Lazear of the American commission and Myers of Liverpool, who fell victims to the deadly diseases which they were investigating and might well be said to have given their lives for the good of others. That their labours had not been in vain was shown by the success with which the recent plague was stamped out and Havana and other pest centres had secured exemption. In conclusion, the President said that preventive medicine as a result of the decade's work alone gave sure promise of saving more lives and sparing more misery than could be accomplished by a treaty of universal peace.

A vote of thanks to Dr. Reeve was proposed by Dr. H. BARNES (Carlisle) and seconded by Dr. T. G. RODDICK (Montreal), while Mr. FRANKLIN and Sir JAMES BARR proposed a vote of thanks to the Mayor for the civic reception. The meeting was then adjourned till 8.30 P.M. At the adjourned meeting, which was held in the Convocation Hall, the Address in Obstetrics was delivered by Dr. W. S. A. GRIFFITH on the Teaching of Obstetrics.[1]

WEDNESDAY, AUGUST 22ND.

The second general meeting was held to-day at 2.30 P.M., when the Address in Medicine[2] was delivered by Sir JAMES BARR on the Circulation viewed from a Peripheral Standpoint. The meeting was adjourned until 8.30 P.M., when Sir VICTOR HORSLEY delivered the Address in Surgery[3] on the Technique of Operations on the Central Nervous System.

FRIDAY, AUGUST 24TH.

The final general meeting was held this afternoon at 2.30 P.M., and was fairly well attended, though members of the Congress had already begun to melt away.

THE SECTIONS.

MEDICINE.

TUESDAY, AUGUST 21ST.

The Section, which was very largely attended, met under the presidency of Sir THOMAS BARLOW (London), who in his introductory remarks referred to the honour of the position of president and to the generosity of the Canadian members of the section in the large share of the time at their disposal which they had allotted to the visiting members.

A discussion was then opened by Dr. PERCY M. DAWSON (Baltimore) on

Blood Pressure in Relation to Disease.

He dealt with certain physiological considerations in regard to blood pressure, emphasising some points which are often overlooked and bringing forward new work. The physiological problems involved in blood pressure offered a wide field for discussion; it was necessary therefore to limit his observations to certain selected topics. At the outset he proposed to define certain terms in order to avoid the confusion resulting from the use of the term "blood pressure" without a qualifying adjective. Careful definitions, illustrated by diagrams, were given of systolic blood pressure, of diastolic blood pressure, and of the pulse pressure, the last being the difference between the other two. It was further stated that applying the results obtained in artificial schemata of the circulation the change in pressure in the aorta during a cardiac cycle was proportional to the change of velocity in the vessel during that time, and Dr. Dawson concluded from his experiments that the pulse pressure might be taken as an index of the systolic output of the heart. Considering the work of the heart, this could be represented by the formula $W = MgH$, where W = the work, M represents the output of the heart, g the force of gravitation, and H the mean pressure in the aorta. The mean pressure in the aorta could be estimated by taking the sum of the diastolic pressure in the brachial artery and one-third of the pulse pressure in that vessel; therefore in this determination the only technical proceeding involved was the estimation of the pressures in the brachial artery. Dr. Dawson indicated the essential requirements of a good instrument for this purpose and emphasised the necessity of determining both the systolic and diastolic blood pressures and of their relation to one another, the difference between them affording the measure of the pulse pressure.

Dr. G. A. GIBSON (Edinburgh) contributed to the discussion a paper on

Clinical Methods of Investigating the Blood Pressure.

He first outlined the various factors in keeping up the blood pressure which should be kept in mind—viz., the initial pressure or energy of the heart, the peripheral resistance (especially that of the splanchnic area), the elasticity of the vessels, the amount of blood in circulation, and the viscosity of the blood. He regarded the so-called *tactus eruditus* as antediluvian and antiquated, and no more to be relied on than the sensations obtained by the hand laid upon a patient's skin would be taken as a gauge of the temperature of the body in pyrexia. He stated as his conviction after 30 years' clinical experience that mere estimation of blood pressure by means of the fingers goes for but little, and that the observation of alterations in blood pressure could only be made by modern instruments. He pointed out that the first observations were made by Vierordt by means of a sphygmograph 51 years ago but that the first noteworthy work on the subject was that of von Basch 25 years ago. He went on to describe the various forms of sphygmomanometer and to classify them according to the manner in which they acted or in which they were applied. The various forms were then criticised and in the case of those encircling the arm the importance of the use of a broad band was insisted on. The instruments of Riva-Rocci and of Janeway gave both systolic and diastolic pressures but Dr. Gibson had found that the only instrument which could be relied upon to give both these values accurately and graphically was the sphygmomanometer of Erlangen, of which he spoke in most enthusiastic terms. The normal limits of these values were in normal persons: for systolic pressures, 90–140 millimetres of mercury; for diastolic pressures, 60–110 millimetres. The influence of various conditions upon these values was described. The effect of posture was so marked that observations should always be made with the patient in the horizontal position; moreover, the time at which the observations were made should be recorded, since the pressures were highest in the morning, although an afternoon rise occurred as well. The influence of food and of occupation had also to be taken into consideration. The observations ought in all cases to be recorded on blood pressure charts.

Sir WILLIAM H. BROADBENT (London) dealt with

The Clinical and Therapeutical Indications of Morbid Blood Pressure.

He differed from Dr. Gibson in regard to the investigation of the pulse by the finger, maintaining that ultimately they would have to rely on the *tactus eruditus*, and further that the real place of the instrumental investigation was in the education of the finger. He referred to the importance of the study of the conditions in the capillaries in regard to questions of blood pressure—notably the intracapillary pressure, the viscosity of the blood, the cohesion between the blood and the capillary walls, and the permeability of the capillary walls. The blood-vessels and their nerves were the servants of the tissues and the variations in pressure and in calibre were due to the requirements of the tissues. The chemical variations in the blood in the capillaries were also of importance in regard to capillary transudation. It was necessary to consider blood pressure from two aspects—first, as it exists in the capillaries, and secondly, in the arterial circulation. It was by the radial pulse that they could estimate clinically the blood pressure on the arterial side of the circulation. Sir William Broadbent then gave an account of the characters of the pulse and the blood pressure as estimated by the finger in various conditions, and pointed out the importance of determining whether the heart or the peripheral resistance was concerned in producing a given rise or fall in the blood pressure; he thought that instrumental indications must always be confirmed and extended by examination of the heart. Various illustrations were then given, among them the lowered blood pressure of pyrexia, in which, in spite of the increased frequency of the heart's action, blood pressure fell because of the diminished resistance at the periphery. The therapeutic indications consisted in the application of the principles enumerated—viz., in the determination of the part played by the heart and the peripheral resistance respectively, and the administration of appropriate measures, such as cardiac tonics in the former case or of nitrites or calcium salts in the latter. The influence of diet, of water drinking, and of mercurials was also considered.

Professor T. CLIFFORD ALLBUTT (Cambridge) then contributed to the discussion a paper on

The Relation of Blood Pressure to Arterial Sclerosis.

He first wished to indicate three points of importance in regard to his own work—viz., that his observations of blood pressure were nearly all made from 10 to 12.30 in the morning, that they were made in his private practice, and that they were invariably made after the ordinary examination of the patient was completed and the circulation therefore more quiet. Arterial sclerosis was not the name of a clinical condition but was rather a term pertaining to morbid histology. Arterial sclerosis was found in a variety of conditions and he recognised three classes or groups—viz.: Class 1. The toxic cases—chiefly in certain infections. The blood pressure varied in this group; in some, as in those cases due to syphilis, it was not raised, while in others, as in lead poisoning, it was increased. Class 2. The hyperpietic group; in these cases there was considerable arterial stress and a large proportion of the cases were the subjects of granular disease of the kidney. Class 3. The involutionary group; chiefly due to senile degradation and associated with trophic or mechanical causes. The blood pressure in these cases only rises to the quasi-normal standard of the age of the individual. These various groups of causes might be combined. Professor Allbutt, having referred to the important work of Traube, von Basch, and Potain in building up our clinical knowledge of arterial sclerosis, outlined his own observations which had led him to the conclusion that high pressure and arterial sclerosis were not a measure of one another, and that arterial sclerosis had little effect in raising blood pressure. He had employed the term "hyperpiesis" to indicate prolonged high pressure, while the hypertrophy of the muscular coat which occurs had been called hypermyotrophy, this latter being a readjustment to counteract the tendency to dilatation of the vessel. Hyperpiesis itself was not a disease but a mechanical adjustment to a diseased condition. In hyperpiesis two different states of the radial artery were found; one in which there was a small straight vessel, and the other with a laxer, more tortuous "leathery" artery. In regard to prognosis in the involutionary cases it was good in regard to length of life, whatever in the course of time might be that diminution of vivacity and adventure which elderly men were pleased to interpret as mellow conservatism, and the tolerant sagacity of experience. The prognosis in the hyperpietic cases was *most perilous. Professor Allbutt strongly* emphasised the importance of the instrumental investigation of the pulse.

Dr. J. Mackenzie (Burnley) contributed some remarks illustrated by pulse tracings on some forms of heart failure consequent upon long-continued high arterial blood pressure. He referred to the five properties of heart muscle described by Gaskell—viz., tonicity, excitability, rhythmicity, contractibility, and conductivity—and illustrated his contentions by reference to a series of cases of arhythmia. He forcibly pointed out the value of the pulse indications in respect of treatment.

Dr. J. Lindsay Steven (Glasgow) supported Sir William Broadbent in his contention that the trained finger was the ultimate appeal in clinical work. He recognised two chief varieties of increased blood pressure, (1) temporary and recurrent, due to errors in diet, mental excitement, constipation, and effort; and (2) a continuous or persistent form associated with chronic Bright's disease, especially the small red kidney. Dr. Steven differentiated between atheroma, which was a focal disease of the aorta and the arteries of the brain, and arterio-sclerosis, which was a generalised affection, especially of the medium-sized vessels. In his opinion high arterial tension might be the result of arterio-sclerosis, but was never the cause of it.

Professor Alexander McPhedran (Toronto) referred chiefly to clinical methods. He supported Dr. Gibson in his contention that the *tactus eruditus* was not trustworthy. He *recommended that the* instrumental determination of blood pressure should be made after quiescence of the patient and at the end of the interview. He had observed a case in which a man was waterlogged to the waist in whom the pulse did not seem to the finger very high, but when measured by a sphygmomanometer it proved to be 280 millimetres of mercury, and it was only little reduced by nitrites. *On the* other hand nitrites yielded favourable results in cases due to arterial spasm.

Dr. G. W. McCaskey emphasised the importance of the factor of peripheral resistance, and the effect of the nitrites in relieving increased *pressure* due to spasm and of their value in diagnosis.

Dr. Alfred Stengel (Philadelphia) read a paper on

Some Clinical Manifestations, Visceral and General, of Arterio sclerosis,

which was taken as part of the general discussion. He had found continuous fever, lasting over considerable *periods* of time, in arterio-sclerosis without any local lesion to account for it, such as pyelitis or other infection. He regarded the fever as possibly due to the active disorganisation of the tissues of the vessel wall, on the analogy of ferment fever. He referred to the occurrence of fever in aneurysm and in cases of acute aortitis. He had also observed suggestive symptoms in abdominal arterio-sclerosis. The patients suffered from repeated attacks of cramp-like pain, with marked intestinal distension and constipation, the attacks sometimes proving fatal, when atheroma and even thrombosis of the mesenteric vessels were found at the necropsy. Max Buch of Vienna had recently described 25 cases of this kind and regarded some of them as due to arterio-sclerosis of the abdominal vessels, others as an abdominal manifestation of angina pectoris. The ulceration of the intestine not infrequently seen in chronic nephritis Dr. Stengel was of opinion is associated with the arterial disease existing in that condition.

Dr. William Ewart (London) spoke on the relation of chronic disease of the arterial wall to the pathological and physiological factors of increased arterial tension—notably of the intermittent factor of muscular work and of the fatigue toxins associated with it and of the continuous factor of the toxins of disease or of disturbed metabolism. He referred to the importance of adequate sleep in regard to arterial spasm and strain, allowing the *vessels to* relax and lessening the work to be done.

Wednesday, August 22nd.

A joint discussion was held with the Section of Physiology on

Over-nutrition and Under-nutrition, with Special Reference to Proteid Metabolism.

The discussion was opened by Professor Russell H. Chittenden (Yale) who pointed out that at the outset they were confronted with the inquiry as to what were the normal requirements of the body for food. In a general way it might be said that a man required enough food to establish physiological and nitrogenous equilibrium and sufficient to maintain that strength of body and mind which was essential to good health, and to afford the highest degree of physical and mental activity with the smallest expenditure of energy, and at the same time to preserve and heighten if possible the ordinary resistance of the body to disease-producing organisms. The smallest amount of food which would secure these ends would be, in his opinion, the ideal diet. Certain dietary standards had been generally accepted throughout the civilised world based largely upon the general experience of mankind, and the experiments of Voit and his pupils had apparently lent scientific authority to these. In the present discussion it would be profitable to consider whether the ordinary dietary standard conformed to the conception of the amount of food necessary to effect the ideal conditions just described, confining attention to the proteid or nitrogen requirements and considering the Voit standard of 118 grammes of proteid daily for the ordinary man of 70 kilogrammes weight. *This* amount was practically 105 grammes of absorbable proteid or 16 *grammes* of nitrogen, which was equivalent to 1·5 grammes of proteid per kilogramme of body weight. Physiologists usually considered that when an organism was in a state of nitrogenous equilibrium the body as a whole and its separate organs were being duly nourished as regards nitrogen. The maintenance of a nitrogenous equilibrium at a low level of intake of nitrogen might be of interest as affording a clue to the minimum quantity of proteid food necessary to repair the nitrogenous waste. It must be admitted as possible that some excess of proteid food over and above the smallest amount necessary to establish nitrogenous equilibrium might be desirable for the maintenance of good health, although *there* was no conclusive evidence of this. Many experimenters, among them Hirschfeld, Kumagawa, and Breisacher, had studied the effect of lowered nitrogenous intake *for* brief *periods of* time, and had demonstrated that it was quite possible to maintain a nitrogenous equilibrium on a diet containing only one-half the amount of proteid food in the Voit scale. *Professor Chittenden had* carried out experiments over extended periods of time in order to meet the criticism that the time was too short to admit of accurate conclusions being drawn. In his own work five professional men were fed for periods of from six to nine months on an average daily *metabolism* of from 5·4 to 8·99 grammes of nitrogen—i.e., 34 to 56 grammes of proteid per day. In three of the cases, individuals of different body weight, there was a close agreement *in the amount* of nitrogen required, which was 0·1 gramme, 0·093 gramme, and 0·102 gramme respectively per kilogramme of body weight, the other two cases requiring somewhat more—viz., 0·14 and 0·139 gramme of nitrogen per kilogramme of body weight, which was not more than half of the Voit standard. Moreover, in these experiments the non-nitrogenous food was *not* increased in quantity. Further, to meet the criticism that such diets could not be borne indefinitely one of the subjects had lived at that level for four and a half years, and, as he believes, with great gain to himself. Similar results had been obtained in 11 soldiers from the hospital corps of the United States army, also with a third group of men, eight in number, mostly athletes, in whom the nitrogenous intake was reduced to from 0·108 to 0·134 gramme per kilogramme of body weight per day. Professor Chittenden was of opinion that 0·1 gramme of proteid capable of metabolism per kilogramme represented the minimum proteid requirement, *but it* would probably be advisable to adopt a standard somewhat above this figure and to *give from 50 to 60* grammes of absorbable proteid to a man of from 60 to 70 kilogrammes weight—i.e., a reduction of about 50 per cent.

Professor W. D. Halliburton (London) said that the large attendance at the discussion was the best evidence of the importance of the subject. In general he was in agreement with most of Professor Chittenden's conclusions, and there could not be any doubt that among meat-eating nations many people eat too much and harmfully in excess. He pointed out that observations on animals in this regard though suggestive were not conclusive—e.g., the dog, an animal with high proteid intake, and the ox, an animal with a low one, were both strong animals. The special feature of Professor Chittenden's observations was the fact that they were made on the human subject and over prolonged periods of time. He instanced the dietary of the poor in large cities and the low nitrogenous intake in vegetarian nations, and stated that it was maintained that such people showed less resistance to privation and to bacterial invasions than meat-eating people. He had been interested to read that Lafcadio Hearn, in writing of the Japanese, attributed their recent vigour and success to their tendency to give up vegetarianism and take larger quantities of animal food. Professor Halliburton further instanced the effect of overfeeding in the open-air treatment of pulmonary disease and in the rest cure for neurasthenia. Proteid in the body served two chief purposes; first, to repair waste of the tissues, and secondly, to act as a source of energy just as fats and carbohydrates do. He was of opinion that if we reduced the amount of proteid to that minimum necessary to subserve the first of these functions we should be dangerously near the margin. He quoted some views of Dr. Leathes who had pointed out that in infants ten times the minimum quantity of nitrogen necessary to repair waste was taken in the diet, even allowing for growth, and therefore asked if it would be physiological for the adult to live too near the minimum.

Dr. OTTO FOLIN (Waverley, Mass.) considered that the important question was to consider the validity of the standards of diet which had prevailed for the past two generations based on the work of Voit and his pupils. Their conclusions had been repeatedly disposed of and yet the Voit standard had remained, the reason being that there was a conviction that the more effective portions of mankind indulged in a diet of this kind, and thus Voit's experiments lent scientific dignity to a popular belief. Statistics were often invoked in support of the contention that the majority of people adopted a diet conforming to the Voit standard, and that greater consumption of food was associated with greater productive capacity. Such statistics required scientific examination since they proved too much. Nothing would be more conducive to advance in this field of work than a frank acknowledgment of our uncertainty and ignorance in regard to the problems of nutrition, while to bring forward the general experience of mankind, a special case of the survival of the fittest, as an argument in favour of a high nitrogenous intake was as rational as to invoke the same argument in support of the use of alcohol, tobacco, tea, and coffee. The optimum proteid diet would probably be between the two extremes, but at present there were no data to enable them to determine this amount, and it would be wise to recognise this.

Dr. ROBERT HUTCHISON (London) contended that the problems of nutrition could not be solved by either the physiologists or the physicians alone, but that it required the coöperation of scientific and clinical workers. The physician and the physiologist approached the matter from entirely different points of view: the physiologist dealt with the normal, ideal or average, whereas the physician with the abnormal, with idiosyncrasies, and with the diseased organism. The physiologist asked what was the proteid minimum, the physician required to know what was the proteid optimum, and these were not necessarily the same. He fully accepted Professor Chittenden's results as regards the minimum and paid a tribute to the American workers in the investigation of nutrition, but he would not accept any suggestion that the optimum and the minimum were the same. It was of interest to notice that in the body there was a tendency towards a reserve, and he would quote the French proverb, "*Pour avoir assez il faut avoir trop.*" It would be of interest in the future to ascertain in persons taking a lessened nitrogenous diet the opsonic index in regard to various disease-producing organisms and the way in which such individuals passed through an acute illness. At present the physician was perplexed by the various statements made in regard to the relation of various diets to disease. In regard to the low nitrogen diet it was stated that gout and rheumatism were relieved by it, while others maintained that a vegetable diet would effect the same end, while recently another school had maintained that one of the main faults in our diet was an excess of fat and carbohydrate rather than of proteids. He further discussed the question of over-nutrition in regard to the fats and pointed out that under the conditions of civilised life there was less use for fat than in the savage state of man. Another point which physiologists were liable to overlook was that of the individual peculiarities or idiosyncrasies. It was important for us to know whether the fact that some persons remained thin on large diets while others could not reduce their fat in spite of very small ingestion of food might not be due to some individuals being more economical machines than others.

Professor L. LAPICQUE (Paris) referred to the effect of climate on diet.

Dr. C. B. RAMARAO (Madras) gave his own personal experience. As a Brahman and a member of a community prohibited from partaking of animal food, he lived on an entirely vegetarian diet and was of opinion that vegetable proteins could be as effectively digested and assimilated as those of animal origin. He instanced the fact that thousands of his countrymen lived in perfect health, carrying out good mental and physical work in their own spheres, who had never touched animal food.

Sir JAMES GRANT (Ottawa) maintained that more people died from excess of food than from excess of alcohol, but stated that in the cold climate of Canada more food material was required than in the Tropics.

Sir THOMAS BARLOW congratulated Professor Chittenden and expressed the gratitude of physicians to him for his elaborate and exhaustive researches The results obtained demanded a reconsideration of the whole subject and would doubtless eventually modify the customs of the profession and the laity. There were two or three points which would occur to practising physicians as requiring solution. One was the reason of the marked improvement resulting in the condition of a child fed on cereals and milk for two years when meat was added to the dietary. Another was the rapid improvement in the process of convalescence from many diseases when meat was given to the patient, and a third was the beneficial effect of overfeeding in pulmonary tuberculosis and neurasthenia. Professor Chittenden recommended a diet which was above the minimum and he (Sir Thomas Barlow) would ask whether there were not a place in the economy for an excess of proteid above the minimum requirements.

Professor CHITTENDEN, in reply, thought that one of the objects achieved by the discussion was that a clear appreciation had been obtained of our lack of knowledge regarding the fundamental problems of nutrition. One of the aims of his work had been to discover whether data based upon the general experience of mankind were in absolute harmony with the physiological requirements of the body. It was also possible that some of the ills of mankind might be ameliorated by living nearer to the low level of proteid metabolism. In regard to the improvement brought about by meat added to the diet of children and convalescents, he suggested that the extractives of meat might play a part in this. In referring to the difference between animal and vegetable proteids in diet it must be confessed that they knew little. That there was a great difference in their constitution was certain, since a vegetable proteid would yield as much as 37 per cent. of glutaminic acid on decomposition, whereas meat proteids yielded only 11 per cent.

Dr. L. F. BARKER (Baltimore) read a paper on

Amino-acids and Metabolism.

He pointed out that the application of chemical study to the problems of biology had yielded great results and especially of late in regard to the structure of proteids All consisted of long chains of relatively simple bodies called amino-acids into which they could be split. More than a dozen of such bodies had been obtained from egg albumin. The amino-acids could, moreover, be artificially chained together and bodies were obtained with characters closely approaching those of proteids—especially the peptones. There were both mono- and di-amino-acids and some 20 of these bodies were now known in the laboratory, among them glycocoll, leucin, tyrosin, lysin, and arginin. A study of the amino-acids present in various forms of proteid food revealed the interesting fact that a human being took about the same quantity of these bodies, whether fish, white meat, or the ordinary meats be taken. The chemist by synthesis was now preparing from these a series of substances called peptides—viz., dipeptides, tripeptides, and polypeptides. It was now recognised that the effect of ferment was to break proteids down into simpler and simpler bodies, the reason being that every animal possessed its own specific proteids and used other proteids in order to build up its own waste; therefore, these proteids were broken down into these amino-acids and then re-united to form the specific proteids of the animal's body. There was now evidence that each cell of the body had to take the serum proteids and break them down again in order to build up its own specific proteids. The question arose as to the fate of superfluous amino-acids. They were oxidised and got rid of as urea. The study of these problems was likely to throw considerable light upon some forms of disordered nutrition, such as cystinuria and alkaptonuria.

Dr. W. B. THISTLE (Toronto) read a paper on

The Treatment of Typhoid Fever.

He discussed the possibility of limiting or preventing the intestinal lesions of the disease and detailed his own practice of giving purgatives and antiseptics throughout the course of the disease. The suggestion made was that purgatives insured increased elimination of the typhoid organisms and their toxins and that therefore they were likely to be of use as in uræmia and lead poisoning. He gave a few grains of calomel and some salol. In his opinion purgation, especially early in the course of the disease, was of great importance.

Dr. W. CALWELL (Belfast) avoided giving purgatives to typhoid fever patients in any form. He quoted some statistics of 150 consecutive cases, showing that the mortality in cases with constipation was very slight, whereas in cases with diarrhœa it was much greater.

Dr. T. M'CRAE (Baltimore) pointed out that the view that typhoid fever was to be regarded as a blood or general infection was gaining ground and that the intestinal lesions were on this supposition to be looked upon as secondary, and as a consequence purgatives were hardly likely to be of value in diminishing the intestinal ulceration. As regards the use of antiseptics he was of opinion that they were of no value because it was impossible to give sufficient quantities to exert any beneficial action. In his experience the elimination of organisms and toxins took place much more through the kidneys than by the bowel, and the good effects of bath treatment were probably due in no small degree to the increased elimination induced by it through the kidneys.

Dr. W. H. NEILSON (Milwaukee, Wisconsin) referred to a case of typhoid fever treated by himself in which severe intestinal hæmorrhage occurred. He induced constipation over a period of nine days and yet obtained no evidence of intoxication from intestinal absorption. The patient recovered.

Professor MCPHEDRAN opposed the use of purgatives, insisting that typhoid fever was a general disease.

Dr. BARKER pointed out that after recovery from typhoid fever large numbers of bacilli might remain in the body and that therefore the mere number of organisms present in the intestine could not be regarded as of great importance in regard to the disease.

Dr. J. H. HAMILTON (Erin, Ontario) was of opinion that purgatives were of value but that they should only be given early in the disease. He also believed in the use of intestinal antiseptics.

SURGERY.

WEDNESDAY, AUGUST 22ND.

The special discussion on

The Surgical Treatment of Ascites Secondary to Vascular Cirrhosis of the Liver

was opened by Mr. SINCLAIR WHITE (Sheffield). He said: Surgical intervention for the relief of cirrhotic ascites is based on well-known anatomical and pathological data. Normally there are four sets of anastomotic vessels uniting the systemic and portal venous systems. These comprise: 1. Veins running in the falciform and round ligaments of the liver—the so-called accessory portal system of Sappey—which connect the portal vein with the epigastric, the internal mammary, and the diaphragmatic veins. 2. The anastomoses between the gastric and œsophageal veins. 3. Veins between the superior and middle and inferior hæmorrhoidal veins. 4. Retzius system of veins situated in the retro-peritoneal tissue, and especially well developed behind the pancreas, the transverse portion of the duodenum, and the vertical portions of the colon. The enlargement of the normal anastomotic veins occurs with great constancy in cirrhosis of the liver and is occasionally associated with newly formed veins running in adhesions between the viscera drained by the portal vein and the abdominal walls. Pathologists have long been familiar with the fact that typical cases of cirrhosis of the liver may run their course to a fatal issue without the advent of ascites provided the collateral circulation is well developed. Drummond and Talma, impressed by the part played by the veins of new formation in warding off ascites, conceived, independently of each other, the idea of creating adhesions between the abdominal viscera and the parietes. Of these the great omentum, both by reason of its vascularity and flexibility as well as by nature's example, appeared to be specially adapted for the purpose and operative procedures for the relief of ascites, however they may differ in detail, always include fixation of the omentum to the abdominal wall. The operation was first performed, at Talma's suggestion, by Van der Meulen in 1889, but with a fatal result. The first successful case was operated on by Rutherford Morison in 1895. This patient lived for two years without recurrence of the ascites. Death followed 48 hours after a trivial operation for ventral hernia and a post-mortem examination revealed the existence of numerous new veins running between the liver, the spleen, the omentum, and the abdominal walls.

In regard to *pathology*, the chronic inflammatory changes induced by the poison, whether it be alcohol or some other agent, lead to degeneration of the hepatic cells and proliferation, with subsequent contraction of the connective-tissue framework of the liver. The latter in turn interferes with the circulation of the blood through the hepatic terminals of the portal vein. Side by side with these pathological changes in the liver there may be developed a more or less extensive chronic peritonitis, and when the incidence of the poison is specially marked on the peritoneal covering of the liver we get perihepatitis. So far there is general agreement among pathologists, but as to the immediate cause of ascites in cirrhosis of the liver two widely divergent opinions prevail. The commonly accepted view is that it is largely a passive effusion of blood serum; that it appears in cirrhotic cases when the enlargement of the collateral circulation fails to keep pace with the ever-increasing portal constriction; that while contraction of Glisson's capsule is the principal cause of obstruction it may be supplemented by partial or complete thrombosis of the portal vein; and that systematic circulatory defects, such as valvular lesions of the heart, may aid the local causes of blood stasis. On the other hand, Hale White, Rolleston, and others reject the doctrine of passive effusion, giving as their most important reason for so doing the negative results obtained in experimental ligation of the portal vein in animals. They allege that the peritoneal dropsy of uncomplicated cirrhosis of the liver is due to the presence of toxic substances in the blood; that these bodies possess lymphagogue properties and are the outcome of defective metabolism on the part of the liver, whose damaged cells are no longer able to arrest and render harmless poisons absorbed from the alimentary canal, or possibly produced elsewhere. They further allege that ascites appears only in the terminal stage of the disease and insist that operative cures in ascites occur only in cases where the peritoneal effusion is the result of chronic peritonitis and perihepatitis. Looking at the subject from a practical standpoint, theoretical considerations must give place to ascertained facts, and it is impossible to ignore the testimony of numerous competent and trustworthy observers who by sight and by touch have verified the existence of well-marked cirrhosis of the liver in cases that have, after operation, not only been cured of the ascitic condition but have for years enjoyed a fair measure of health. Moreover, numerous instances have occurred where a subsequent laparotomy for some other condition has enabled the operator to examine the remote effects of epiplopexy on the collateral circulation and to testify to the remarkable increase of the anastomotic vessels which it produces. The evidence thus afforded, conjoined with post-mortem observations on cases that have run their course without the appearance of ascites, leaves no doubt that stasis of blood in the portal system is the most important factor in the production of cirrhotic ascites.

The operation involves more or less traumatism to the liver, the omentum, and the peritoneum, and, however carefully done, causes some degree of shock. It should therefore, apart from special objections, not be performed on old or on very feeble patients. It is contra-indicated in Bright's disease and in diabetes, but the temporary presence of a small amount of albumin or sugar in the urine may be ignored.

A scanty excretion of urine is nearly always associated with ascites and need not weigh against operation, but if the total amount of urea is very greatly reduced it would, according to some writers, militate against operation on the ground that the liver being the chief centre of the manufacture of urea a very much reduced output indicates advanced hepatic disease. Persistent jaundice, even if slightly marked, and mental hebetude are two most ominous symptoms and the presence of one or both should preclude surgical interference. The same observation applies to serious organic disease of the heart and lungs. Cirrhotic patients are unduly prone to tuberculous disease and special care should be exercised to exclude phthisical cases. Acholia and urobilinuria, if pronounced, are excluded by Talma in his list of objections to operation. He also looks on well-marked xanthoma as an unfavourable sign. The ascites of atrophic cirrhosis is said to be less hopeful than that associated with the hypertrophic type but an analysis of the cases I have tabulated fails to show this. In all cases tapping should be resorted to once or oftener before proceeding to operation. In a small minority of cases this alone will effect a permanent cure of the ascitic condition and in all it will help the operator to gauge the personal equation of his patient.

As to *operative details*, omental fixation enters into every recognised method and is universally conceded to be the most important step in the operation. Additional procedures consist in "rawing" the peritoneal surfaces of the liver and spleen together with the opposed peritoneum lining the under surface of the diaphragm and anterior abdominal wall, with or without anchoring sutures. A variation of the process in respect of the spleen is to create a rent in the parietal peritoneum and effect a subperitoneal displacement of this viscus. Hepatopexy can be easily and rapidly performed through the incision required for fixing the omentum but the spleen is less accessible through this opening and the steps necessary for dealing with it involve so much disturbance that its inclusion in the operative programme is not desirable. If for any special reason splenopexy should be deemed necessary it would be better to perform it through an independent opening and, by preference, on a subsequent occasion. Of the methods of treating the great omentum two in particular have received special recognition. One, the method described by Morison, is to fix its anterior surface by numerous point sutures to the opposed parietal peritoneum previously freshened by vigorous gauze rubbing. The other, devised by Schiassi of Bologna, aims at placing the omentum between the parietal peritoneum behind and the posterior surface of the abdominal muscles in front.

The *results of operation* are as follows. Professor Monprofit, in an exhaustive paper presented to the French Surgical Congress in 1904, tabulated 224 cases of the operation collected from various sources. Of these 84 died within one month of the operation, equalling a mortality-rate of nearly 38 per cent. The writer had collected particulars of 227 cases operated on. Of these 33 per cent. died within one month of the operation, 15 per cent. were failures, 13 per cent. were improved, and 39 per cent. were cured of the ascitic condition. The frequency with which peritonitis occurred after operation suggested that in cirrhotic ascites the resistance of the patient to bacterial invasion was lessened.

Mr. G. Grey Turner (Newcastle-upon-Tyne) referred to the unavoidable absence of Mr. Rutherford Morison. A record was presented of all the cases that had been operated upon in Newcastle-upon-Tyne since Dr. Drummond and Mr. Morison had their first case in 1894. In all there had been 16 operations and of this number five patients died within a few days, three from pneumonia, one from uræmia, and one from cholæmia. None of these fatal cases had been properly selected. Of the 11 that survived the operation five had subsequently died, at periods varying from four months to six years and three months after operation, thus leaving six patients to be accounted for, and of this number the after-history of five was presented. One patient was well seven years and five months after operation, another was alive but with recurrence of symptoms three and a half years after operation, and three were perfectly well two years and seven months, 12 months, and seven months respectively after operation. 16 cases with only five patients alive 12 years from the date of the first operation did not appear to be a good record, but it was pointed out that of these 16 cases only six fulfilled the conditions insisted upon by Drummond and Morison, and of these properly selected cases three were alive and well seven years and five months, 12 months, and seven months after operation; two lived in good health for five years and two years respectively, in both cases death being due to accident or intercurrent affection; and one case could not be traced. Mr. Turner insisted that the success of the operation depended upon the proper selection of cases, only those suffering from alcoholic cirrhosis who were free from other visceral complications and who had survived one or two tappings coming into this category. Many cases of ascites not due to alcoholic cirrhosis had been cured by the operation, but it was contended that in arriving at a proper estimate of the operation as originally suggested these ought to be excluded, for many of the fatal cases came from this group. In the technique stress was laid on the importance of continuous drainage and strapping. One of the most important questions for discussion was the influence of the operation on the cirrhosis itself.

Mr. John Lynn Thomas (Cardiff) read a paper on

Enucleation of the Prostate.

The revival of prostatectomy, he said, had proved a remarkable success and as a consequence the last five or six years had seen a sufficient number of operations of the kind from which, as data, to discuss the respective merits of the two main methods of surgical procedure. As this comparison was the point of greatest practical interest he would therefore proceed rapidly to its consideration after a few preliminary remarks upon the diagnosis of hypertrophied prostate. For diagnostic purposes there were only two means by which the character of an enlarged prostate could be determined before operation: (1) palpation per rectum and (2) investigation of the length of the urethra. Where no elongation of the urethra was present the cystoscope might also offer a possible third method of examination but he had not found its use of value in ordinary cases where elongation occurred. Proceeding by these methods it was possible to exclude certain cases of enlarged prostate as unsuitable for enucleation. In what circumstances should the prostate be enucleated? In dealing with this question Mr. Thomas expressed himself in favour of operation as soon as the patient was compelled to face the risks of "catheter life." Notwithstanding a great improvement in the directions now given to patients entering upon "catheter life" the risks still remained so great as considerably to exceed those of immediate operation. Proceeding to a comparison of the results obtained by perineal and suprapubic prostatectomy respectively, Mr. Thomas referred in detail to a large series of statistics which, with the assistance of Mr. A. Clarke, he had been able to compile from English, American, and European records of cases. A total of 677 perineal operations provided 89·8 per cent. cases of recovery, and a total of 583 suprapubic operations 88·9 per cent. In complete cures, however, the suprapubic method showed a greater percentage, 95·6 per cent. against 81·4 per cent. of the cases of recovery after the perineal operation. Thus, although the perineal method gave 0·9 per cent. more cases of recovery the suprapubic method gave 14 per cent. more cases of complete cure. The advantage of the perineal route would seem to lie in the greater ease of drainage. Difficulties of drainage, however, only made themselves felt in the case of the suprapubic operation when dealing with septic cases. With a septic bladder it became necessary to drain the cavity from which the prostate had been removed by an *additional perineal incision*. Better still, however, was a method more in accord with the canons of general surgical procedure. It was a *most* valuable general principle to avoid operations through inflamed tissues except in cases of necessity. *Deference* to this principle involved an operation carried out in two stages. The first step was the performance of a suprapubic cystotomy, the second, removal of the prostate, this not being undertaken until the parts were restored to their normal condition of asepticity. Free drainage by cystotomy was preferable to irrigation and medication of the bladder through the catheter. As to the technique of the operation Mr. Thomas was in favour of a transverse incision of the skin, &c., with vertical separation of the recti. A silver prostatic catheter was passed into the bladder as a guide during enucleation, and as soon as the viscus was opened a special spoon-shaped retractor was used to elevate the prostate per rectum. Mr. Thomas summarised his remarks in the following series of conclusions:—1. That there is no choice between the suprapubic and perineal methods of enucleation so far as the incidence of mortality was concerned. 2. That either method may be followed by disappointing results, such as stricture of the urethra, urinary or recto-perineal fistulæ, and interference with the sexual functions. 3. That in septic cases enucleation of the prostate should be performed in two stages. 4. That the suprapubic route is more suitable for tumours of the middle lobe, for the removal of calculi, and for the control of hæmorrhage when such complications are present. 5. That the suprapubic route is unsuitable for surgeons with short fingers or flexible nails. 6. That post-mortem evidence fails to justify the contention that enucleation had ever resulted in the complete removal of the prostate. 7. That anatomical evidence was conclusive in demonstrating the impossibility of removing the prostate in one mass without also removing the prostatic urethra.

Mr. GEORGE A. BINGHAM (Toronto) also read a paper on the same subject. He dealt first with the minute structure of the normal prostate, referring in some detail to the structure of the prostatic stroma and its relationship to the glandular elements. Reference was also made to the question of a middle lobe, to the lack of a true capsule, and to the absence of definite lobes. The developmental history of the gland was such as to make evident its purely sexual function. There was no special thickening at the neck of the bladder capable of acting as a specific sphincter. Dealing with the subject of hypertrophy, he emphasised the fact that the majority of prostatic tumours were simple adenomata. In his opinion the normal tissue of the gland was displaced by the new growth and was driven to its periphery, thus giving rise to a pseudo capsule. The process of enucleation was always performed by separation along some line of cleavage between the different strata of this spurious capsule. Discussing the treatment of hypertrophy, he divided the cases into three classes: 1. Early cases where in an otherwise healthy man the only symptom was obstruction to the urinary outflow. Here removal by operation was advised. 2. Very late cases where kidney or bladder complications forbade a formal prostatectomy and yet some surgical intervention was urgently demanded. In such cases the Bottini operation was of value, performed under a local anæsthetic. When the patient's general condition was bad and complicated by the presence of a calculus, either in the bladder or in the prostate, suprapubic cystotomy was advised under local anæsthesia. When the stone had been removed the Bottini instrument was applied under the guidance of the finger in the bladder. 3. Intermediate cases where the general condition was good but cystitis, calculus, incontinence of urine, prolapsus ani, &c., rendered life a burden. Here the radical operation was advised, the choice of route being altogether determined by the conditions present. Thus when the middle lobe alone was involved and the resulting tumour projected into the bladder the suprapubic method was followed. When, however, the mass bulged towards the perineum and rectum the perineal method was chosen. In the performance of these operations it was essential to pay attention to "ante-" and "post-operative" treatment if good results were to be obtained. In conclusion, reference was made to the treatment of shock and uræmia, the most common causes of death, and to the most recent statistics, which showed slightly more favourable results from the perineal method of operation.

The discussion which followed revealed a very decided preference on the part of American surgeons for the perineal route.

Dr. G. E. ARMSTRONG (Montreal) reported

The Successful Removal of the Spleen in a Case of Banti's Disease.

The patient had recovered full health and strength and the blood had returned to practically a normal standard. A very unusual and interesting feature in his case was the incidence of a condition of tetany coming on about 12 hours after the operation. Painful spasms involving the trunk and extremities continued to occur at intervals for about 40 hours, when they ceased completely. Of 32 cases of splenectomy in Banti's disease 23 recovered and nine died—a mortality of 28 per cent. The larger number of cases occurred between 10 and 40 years of age. The recovery in the successful cases would seem to be permanent, with complete relief from attacks of hæmatemesis and apparently an arrest of the cirrhotic changes in the liver and a return of the blood to a normal condition. Attention was particularly drawn to the enormous dilatation in the splenic veins and the alteration in their walls, leading to stasis and passive hyperæmia of the spleen and dilatation of the vasa brevia and œsophageal veins. It was suggested that the changes in the veins might be one of the earliest lesions and possibly secondary to some alteration in the gastric mucosa. The changes in the spleen would then be regarded as secondary to the persistent blood stasis and hyperæmia. Splenectomy was urged as the proper method of treatment. It should be done before the changes in the liver become pronounced.

GYNÆCOLOGY AND OBSTETRICS.

TUESDAY, AUGUST 21ST.

Dr. A. H. FREELAND BARBOUR, the President of the section, delivered some introductory remarks on

The Relation of Gynæcology to the Work of the General Practitioner.

He said that gynæcology as a specialty was sufficiently in evidence in the programme of work of the section and therefore he devoted the few minutes of his introductory address to the relation of gynæcology to the work of the general practitioner. The medical student started with a wrong idea of gynæcology, for which the term "diseases peculiar to women" was in part responsible. Instead of applying the general principles of pathology to pelvic disease he thought that these had a special pathology. There was no more reason to treat gynæcology as a specialty than obstetrics, which was admitted to be part of the work of the general practitioner. A moment's consideration would show that the great majority of gynæcological cases must be at first in the hands of the general practitioner. The recent remarkable development in operative gynæcology had led to the idea that the surgical aspect of gynæcology was gynæcology itself. But that was only one side of it; it had what he might call its medical aspect also. Gynæcology was not a specialty in the same sense as mental disease or even diseases of the eye. When a case of mental disease presented itself the practitioner at once recognised that here was a case which did not belong to him. And the same was largely true of diseases of the eye. Specialism in gynæcology, apart from major gynæcological operations, was more akin to specialism in diseases of the heart or lung, in which, by devoting special attention to affections of one system and gaining a wider experience in it than fell to the general practitioner, the physician had come to be recognised as an authority on diseases of a given system. From this point of view it might be said that the way to the specialist in gynæcology passed through the domain of the general practitioner and that the specialist was to be called in when the general practitioner recognised that he had not the training or experience to enable him to diagnose or to treat successfully his patients. This view of the subject required a higher standard of knowledge than he at present possessed, and they stood at the parting of the ways. Was gynæcology to be relegated to the post-graduate course, to be studied only by those who had a bias towards it? Or was it to be made an integral part of the student's training, so that at its termination he would know at least the elements of clinical gynæcology? From the relation of the diseases of women to obstetrical work, from the reasonable expectation of the general public, from the very nature of the case it seemed to him that the student must be taught and examined clinically. It should be taught in relation to medicine, surgery, and midwifery, the tripod on which the practice of medicine rested. If these three subjects were represented by three circles side by side gynæcology was a fourth intersecting the three. Specialism was a peak in a mountain range and its development was subject to the same law. A broad foundation must be laid for knowledge, remembering that the height of a hill was related to the breadth of its base. Some rose, like Fujiyama, abruptly from the plain, volcanic in nature, produced by a sudden outburst of imprisoned force. Such were the geniuses of the medical profession. More usually, however, a peak was produced by a gradual process—for nature was rarely in a hurry—which led to its appearance as a member of a mountain chain. The specialist was slowly differentiated from his fellows like a peak in the Rocky Mountains.

After the President's introductory remarks, Professor ADAM H. WRIGHT (Toronto) read a paper on

Concealed Accidental Hæmorrhage.

He dealt only with that type of concealed hæmorrhage which occurred in the latter part of pregnancy before the effacement or dilatation of the cervix. Many such cases were overlooked and the condition was more common than was formerly supposed. Five cases had come under Professor Wright's observation and he proceeded to give a clinical picture of the condition, stating that colic was one of the predominant features and that there might be nothing to draw attention to the uterus as the seat of the lesion. The patient was in great danger until the uterus was emptied, but how to empty the uterus was by no means an easy question to settle. Dilatation of the cervix might take as long as two hours and in its attempt the woman might die undelivered. The chief aim of Professor Wright was to show that in a certain number of cases the symptoms were due to shock only and not to loss of blood, and cases were cited to illustrate this view. Reference was made to the treatment by *accouchement forcé*, Professor Wright's view being that it was an extremely dangerous procedure. Treatment by friction, electricity, nitro glycerine, amyl nitrite, ergot, quinine, rupture of membranes, steel dilators, various kinds of dilating bags, and the vaginal plug were all to be avoided. Professor Wright gave morphine for the shock to the extent of one grain in one hour; the physician's aim should be to give the morphine before profound shock had been established. To the first dose of morphine $\frac{1}{150}$th of a grain of atropine was added. The patient's head should be lowered and the body temperature maintained by the external application of artificial heat Salt solution should be administered by high enema. Small doses of strychnine, $\frac{1}{30}$th of a grain per hour, were to be given, but large doses of this drug were exceedingly dangerous. By such means as these the patient was got into a better condition for operation. The operation advised by Professor Wright was vaginal or abdominal Cæsarean section.

Dr. W. S. A. GRIFFITH (London) said that in his opinion the discussion of the treatment of accidental hæmorrhage suffered from being considered apart from that of placenta prævia hæmorrhage, the principles of which were almost the same. Cases might be divided into two groups—those in which the hæmorrhage was little and the danger little, and those in which it was great and the danger great. The first group was common and the second was very rare. The treatment of the second group was that which raised the chief points for discussion, especially in those in which the cervix was tough and undilatable. In this condition Dr. Griffith believed that section of the uterus, especially vaginal, was the best operative method when circumstances permitted it. In cases of multipara with soft dilatable cervix the treatment of Braxton Hicks, bipolar version with normal dilatation, was the safest method and the most easily performed by the general practitioner.

Dr. TEMPLE (Toronto) said that the treatment of accidental hæmorrhage of the concealed variety depended entirely on the gravity of the symptoms. If it occurred at the time of delivery the uterus should be emptied as soon as was consistent with the patient's condition either by version or some other method. If it occurred during gestation and the symptoms of shock were very severe, with the os hard and unyielding, the safest plan was to rupture the membranes, apply a firm pad and bandage over the uterus, give restoratives, and deliver the patient later. He had never seen any case calling for such radical treatment as vaginal or abdominal Cæsarean section.

Dr. MURDOCH CAMERON (Glasgow) agreed with Dr. Griffith that if proper assistance was at hand no anxiety need be entertained about the termination of the case. His treatment was to apply a tight bandage, plug the vagina, give opium, and after the patient had got over any symptoms of shock to induce labour. He had never seen a death from accidental hæmorrhage. On no occasion in dealing with the case should the de Ribes bag be used, nor would he entertain the proposal of Cæsarean section.

Dr. W. GARDNER and Dr. J. R. GOODALL (Montreal) communicated a paper on

Chronic Metritis and Arterio-sclerosis of the Uterus.

From a study of nine cases they were able to distinguish two distinct groups. Chronic metritis was divided clinically into simple and complicated. By simple metritis was meant a clinical entity with the symptoms of uncontrollable hæmorrhage and the physical signs of enlargement of the uterus, thickening of its walls, induration, enlargement of its cavity—all these without loss of symmetry. In simple metritis the uterus alone was involved without participation of the other pelvic organs. By complicated metritis Dr. Gardner and Dr. Goodall meant a uterine condition similar to the above but associated with chronic disease of the appendages, with which the metritis might be primarily or secondarily associated. In their paper Dr. Gardner and Dr. Goodall dealt only with chronic simple metritis, which, as already stated, they divided into two groups. Six of these cases fell into the first group, and to this group they applied the term "inflammatory." To the second group, of which they had had two cases, they applied the term "arterio sclerotic." They then proceeded to give the characteristics of the two groups, their description comprising minute and detailed pathology, which would be published in full with their paper.

Dr. ARTHUR E. GILES (London) read a paper on

A Study of 146 Consecutive Cases of Ventrofixation of the Uterus.

He presented some observations on the operation of ventrofixation, based on a series of 146 consecutive cases, divided into groups as follows: Group I., uncomplicated retroversion of the uterus, 47 cases; Group II., retroversion and fixation of the uterus, 26 cases; Group III., retroversion and diseased appendages, 21 cases; Group IV., retroversion and fibroids, 13 cases; Group V., prolapse, 19 cases; and Group VI., total procidentia, 20 cases. The subject was considered with special reference to three points—viz., (1) indications for the operation; (2) technique of the operation; and (3) after-results of the operation. The conclusions arrived at were as follows: 1. Indications for ventrofixation. Dr. Giles regarded the operation as a valuable one—(*a*) in cases of moveable retroversion of the uterus when pessaries had been tried without success; when the uterus retained its position as long as pessaries were worn but fell back as soon as they were removed; and when the patient elected to undergo radical treatment rather than submit to pessary treatment with its attendant frequent examination; (*b*) in cases where the uterus was held down by adhesions in a position of retroversion; (*c*) in cases where a retroversion was complicated by disease of the appendages; and (*d*) in cases of prolapse and total procidentia. Dr. Giles did not suggest that cases of retroversion in the first group should usually be operated upon but was of opinion that about 5 per cent. of such cases would be benefited by operation. 2. Technique of the operation. Dr. Giles laid stress upon the advisability of treating at the same time, whenever possible, co-existing abnormal conditions. thus cases with endometritis should be curetted; a torn cervix should be repaired; a hyperplasic cervix should be amputated; small or solitary fibroids should be enucleated; prolapse of the vaginal walls should be dealt with by colporrhaphy, perineorrhaphy, or both; and diseased appendages should be treated by conservative procedures or by removal, according to the nature of the case. 3 Results of the operation. Dr. Giles had seen and examined 73 patients at periods varying from six months to eight years after the operation. 12 patients had become pregnant, with 16 pregnancies between them, resulting in nine confinements at full term, five miscarriages, and one pregnancy of seven months at the time of reporting. In no case were there any serious complications with labour. In 10 of the 12 cases the uterus remained fixed in good position after delivery; in two there was partial return of the displacement. Among the 61 cases where no pregnancy followed the uterus remained in good position in 58, or 95 per cent.; in three cases there was a return of the displacement. The abdominal scar gave trouble in only 2, or 3 per cent. of cases; there was one case of scar hernia, the other being a case of "stitch-abscess." The general condition of the patient showed marked improvement in about 90 per cent. of cases.

Dr. TODD GILLIAM (Columbus, Ohio) stated that he shared Dr. Dudley's objections to ventrofixation. As the pioneer of operations on the round ligament for ventro suspension he had watched the development of this operation with great interest and from an analysis of many hundred cases a symptomatic cure was a nearly universal result. He claimed that the success of this method was due to the fact that the round ligaments developed *pari passu* with the development of the uterus in pregnancy. No unpleasant sequelæ followed pregnancy or parturition. The uterus was not suspended but anchored, and there was no danger of incarceration or strangulation of the bowel as there was an opening of from through which the bowel might enter or leave. The operation was simple, efficient, and safe.

Dr. J. WESLEY BOVEE (Washington) said that ventrofixation and ventro-suspension substituted one anatomical deformity for another and that he had abandoned both these operations five years ago. Uncomplicated retroversion gave no symptoms and needed no treatment. Complications were the indications for treatment. Dr. Bovee preferred ligamentous operations to ventrofixation. He dealt with both the utero-sacral and round ligaments and also the utero-vesical ligaments. He preferred hysterectomy to ventrofixation in cases of procidentia after the menopause.

Dr. S. N. HAY (Toronto) always curetted before performing ventro-suspension and if the cervix was elongated it should be amputated as it was likely to worm its way into the axis of the vagina and cause displacement. Dr. Hay expressed surprise that Dr. Giles made no distinction between ventro-suspension and ventrofixation. In Canada the fixation operation was reserved for those cases which were beyond the risk of pregnancy. Dr. Hay had opened the abdominal cavity several times at a period of from two to two and a half years after operation, and always found the uterus still in good position, with the central ligament about two inches long still on duty. In one of these cases the patient had gone through pregnancy and parturition in a perfectly normal manner, the uterus remaining afterwards in good condition.

Dr. E. C. DUDLEY (Chicago) said that after an experience of several hundred cases of suspensio uteri—not fixation—in which the posterior wall of the corpus at a point near the fundus was sutured with catgut to the anterior parietal peritoneum near the bladder, he was able to endorse this operation so far as the correction of the displacement and relief of symptoms were concerned. This operation was not, however, anatomical, while that of Dr. Gilliam was anatomical, and the latter was the one which he (Dr. Dudley) now employed. He admitted that further observations were needed to confirm the claim of Dr. Gilliam. He thought that most of the blame laid at the door of suspension properly belonged to fixation.

Dr. TEMPLE believed that ventro suspension was much to be preferred to ventrofixation, the latter being an obsolete operation, whilst suspension was an admirable operation, as it in no way destroyed the mobility of the uterus. Abortion rarely followed suspension, whilst it was common with fixation. Before any such operation was performed preliminary treatment should in all cases be followed, such as curetting or trachelorrhaphy, and so on.

Dr. GARDNER said that the importance of treatment of retroversion could not be over-estimated. Pessary treatment often failed for various reasons and by many patients was rejected if a comparatively safe operation was offered as an alternative. Dr. Gardner objected to ventrofixation in the sense of establishing a form of union of the fundus of the uterus with the abdominal wall. He aimed at creating a somewhat slender ligamentous attachment which permitted of a degree of mobility of the uterus. As regards relief from pelvic pain, it was not to be expected that the more permanent replacement of the uterus would in complicated cases relieve this symptom, which was often due to chronic metritis or to cystic or cirrhotic ovaries. The miscarriages which sometimes followed ventro suspension were not the result of the operation but were due to chronic metritis. Dr. Gardner differed from Dr. Giles in the order of operative procedure. When a number of operations were necessary he thought it was best to curette and repair or amputate the cervix and then proceed to plastic work on the vagina and perineum, if indicated, concluding all by the abdominal operation. Of the various plastic operations on the vagina he thought that Le Fort's operation was a very valuable one in suitable cases, such as an extreme degree of relaxation of the vagina in a widow unlikely to marry and past the child-bearing age There were, however, cases on record of women conceiving and bearing children successfully after this operation.

WEDNESDAY, AUGUST 22ND.

Dr. CHARLES A. L. REED (Cincinnati) made a communication on

Changes in Uterine Fibroids after the Menopause considered with reference to Operation.

The discussion was strictly confined to myomatous and fibro-myomatous growths, to the exclusion of adeno-myomata, the latter being potentially half malignant from the start and liable to become actively malignant. Fibroids were liable to retrogressive as well as to evolutional changes, comprising atrophy, calcareous and fatty degeneration—changes consistent with benignity and with the integrity of the growth. They might, however, become necrotic from pressure or they might be the seat of inflammation and suppuration or more rarely might undergo either myxomatous or amyloid degeneration, changes which destroyed the integrity but did not alter the benignity of the tumour. Too much, then, could not be laid on sarcomatous degeneration. Dr. Reed upheld as correct the statement that fibroids underwent carcinomatous change. Tumours which had a mural or submucous situation tended in general to maintain the menstruation to the age of 50 years or beyond. Dr. Reed cited a case in which it was prolonged to the age of 59 years. Cases in which there was severe recurrent hæmorrhage or in which there was rapid growth of pressure symptoms or signs of suppuration would most assuredly lead all surgeons to advise hysterectomy. But the question of operation upon fibroids during rapid reproductive life could not be solved by set rules. "The practitioner should be governed by the axiom that a fibroid of whatever character was potential only for mischief and that other things being equal it was better out than in the patient." The menopause could not take the place of the surgeon. The idea that a fibroid which had undergone calcareous degeneration had by that change become innocuous, and the hope that all fibroids which could be brought to the menopause would undergo that change was, indeed, the foundation for the let-alone policy which was to-day all too indiscriminately prevalent with the profession. Three cases were cited to show that calcereous fibroids could not be relied upon to remain innocuous. Piquand collected 81 cases of calcified fibroids in which there were 29 accidents due to compression of neighbouring organs, 15 instances of profuse metrorrhagia, and in 18 there was suppuration in the adjacent uterine tissues. An analysis of 26 reported deaths showed five from peritonitis, three from intestinal obstruction, one from retention of urine, one from ureteral compression and consequent uræmia, one from metrorrhagia, one from sudden rupture of the bladder, seven from cachexia the result of interminable suppuration, one from torsion of the uterus, and six in which death was preceded by cancer of the uterus appearing after calcification of fibromata. With regard to the last Dr. Reed seemed to view the cancer as a consequence of the fibroid and again cited a case in support of this contention. In conclusion Dr. Reed stated (1) that the only safe place for a fibroid of the uterus, however small or large, however soft or hard, however recent or old, was outside the patient's body; (2) the menopause was a poor surgeon; (3) certain fibroids of the uterus ought to be relegated to operation without reference to either the nearness or remoteness of the menopause; (4) only in cases in which there was some condition not connected with the tumour itself, and making operative interference a dangerous policy, should the leave-alone treatment be adopted; and (5) patients who chose a waiting policy should be warned of the dangers of taking such a course and should be kept under close and frequent observation.

Dr. J. F W. ROSS (Toronto) said that having listened carefully to Dr. Reed's excellent exposition of this subject, he rose to enter a protest to his conclusions. It was important that the younger men of the profession should be properly guided, and anything that Dr. Reed wrote was read with interest and looked upon as the dictum of an authority, the word of an author who had written an excellent work on gynæcology. He failed to follow his reasoning when he told them that the safest place for a fibroid was out of the woman, unless he went further and said that a degenerating uterus at the menopause was safer out of the patient's body. A fibroid was only an outgrowth of the muscular tissue of the uterus and not a malignant growth, and very seldom, if ever, did it undergo cancerous change. Cancer often accompanied myomatous tumours, but it very frequently occurred in the uterus at or after the menopause when no fibroid tumour was present. He had never satisfied himself that fibroid tumours produced such irritation as led up to cancerous development. Sarcomatous degeneration of fibroids did occur but not frequently. The removal of a small fibroid from a young married woman was a serious operation. An enucleation was not so unfortunate in such circumstances as total removal of the uterus. Total removal prevented a possibility of motherhood; if after this time the same objection did not obtain, and if then malignant disease developed, it was possible and right to remove the organ. When tumours were growing in spite of the menopause they should be removed. He agreed with Dr. Reed in much that he said and complimented him on his excellent exposition of the subject.

Dr. H. T. **BYFORD** (Chicago) called attention to the small number of recorded deaths due to the changes mentioned by Dr. Reed in comparison to the large number of tumours that occurred. Hyperæmia about the tumour and in the mucosa predisposed somewhat to malignant changes, but they did not remove a uterus on account of congestion. Many died without these tumours having been suspected. They knew that the single tumours usually grew fat and underwent myxomatous and cystic degeneration, but the multiple growths were apt to interfere with their own nourishment and did not always grow large, and if still quite small might be watched. If at the menopause the tumours were small they might not grow much, and it then would not matter if they underwent calcareous degeneration —this would be nature's cure.

Dr. **WILLIAM L. REID** (Glasgow) said that they were restricted in this discussion to treatment of fibroids after the menopause. In certain cases fibroids which had been known to exist before the menopause shrank slowly and practically disappeared after it. In other cases they slowly or rapidly enlarged, due either to degeneration of a cystic sort or to general growth of tissue. In the former case they should be left alone but watched at intervals. In the latter they should be removed as being almost certain to give rise to serious symptoms. The former were hard white fibroids, as a rule, with a well-marked capsule of connective tissue; the latter were soft, very vascular, and usually had no marked line between the tumour and the muscular tissue of the uterus.

Dr. **MURDOCH CAMERON** said he regretted very much that he was not present to hear the paper read but from the remarks in the discussion he had formed some idea of the points advanced. On one point he was quite assured, in spite of repeated assertions, that true fibroids did not disappear. In many instances the conditions found justified the greatest satisfaction that operation had been performed. His opinion, therefore, was that early operation should be advised. The logical treatment of all fibroids was the same as that for the diseased appendix—that was early removal, when the mortality should be almost *nil*.

Dr. **W. GARDNER** (Montreal) did not believe that Dr. Reed was so radical in his advocacy of the almost universal removal of fibroid tumours as to include a case such as the following, which he had had the opportunity of watching with the usual medical attendant. This was the case of a woman who became pregnant soon after marriage and as the uterus grew a cluster of sub-peritoneal fibroids appeared on the body of the uterus. This woman had been safely delivered three times. The pregnancy, labour, and puerperium were normal in each case.

Dr. **HENRY O. MARCY** (Boston) said that each patient was an individual factor. In a general way he approved of the conclusions of Dr. Reed. He reported the case of a patient, aged 78 years, in whom there was a large uterine tumour of 40 years' standing. It was supposed to have disappeared and was certainly not felt in the abdomen. The uterus measured nine inches in depth; it was drawn out and removed. An easy recovery followed. A uterine myoma as a rule should be removed. If ever the mortality exceeded 4 per cent. it was due to faulty technique.

Dr. **D. J. EVANS** (Montreal) spoke in favour of a conservative attitude in the question of fibroid tumours. He mentioned a case in which a tumour complicated pregnancy at the third month, causing excessive enlargement of the uterus. This tumour was as large as two fists and was situated on the anterior uterine wall. It remained palpable for about two years, when it disappeared within six months, the patient having been delivered at term. He mentioned three other cases with tumours which he had delivered at term without difficulty and the tumours had since given no trouble.

Dr. **GRIFFITH** referred to two cases of calcified fibroids in old women requiring removal, recorded by him recently in the transactions of the Obstetrical Society of London.

Dr. **JOSEPH PRICE** (Philadelphia) fully agreed with Dr. Murdoch Cameron as to the treatment of fibroids. He criticised Dr. Reed's conservative treatment and considered that removal of single or multifold fibroids could be easily performed by the vaginal route.

Dr. H. L. **REDDY** (Montreal) read a paper on

Indications for Cæsarean Section other than Pelvic Deformities or Tumours.

Cæsarean section was advanced by Dr. Reddy as an operation of election in such conditions as eclampsia and placenta prævia. He regarded this operation as capable of being performed almost anywhere and by anyone, provided the rules of asepsis were followed. His own experience was based on 14 cases, 13 of which were successful, the fatal case being one of deformed pelvis and the patient was in a desperate condition; the child was saved. He advocated a more frequent employment of Cæsarean section than was done at present. It was easier than *accouchement forcé*. Indeed, it was almost as safe as an ordinary confinement. In eclampsia the consensus of opinion was in favour of rapid delivery and in such cases where convulsions had set in early, or at full term, and the cervix was not yet dragged up and the os not yet dilated, the question arose as to what was the best means of effecting delivery. There were four methods of rapid delivery. First, Dührssen's cervical incisions; secondly, dilatation by mechanical dilators, such as Bossi's; thirdly, vaginal Cæsarean section; and fourthly, Cæsarean section proper. In the first method there was danger from infection and hæmorrhage and, moreover, it required a practised accoucheur. In fact, it required more assistance than true Cæsarean section Mechanical dilatation did not mean rapid delivery and led to laceration. Vaginal Cæsarean section had all the objections urged against Dührssen's operation and was still more difficult to perform, whilst abdominal section was simple and easy and practically free from danger. Was Cæsarean section justifiable in placenta prævia? Dr. Reddy stated that it was, especially in placenta centralis. The death-rate of Cæsarean section was to-day from 3 to 5 per cent. and nearly all the children were saved, even in cases of placenta prævia. The following telegram had once been sent to 14 leading physicians in the United States: "In placenta prævia centralis, the patient being a primipara, a child viable, a cervix rigid, free hæmorrhage, surroundings favourable, would you endorse Cæsarean section?" Out of the 14, 11 practically answered in the affirmative, and with this view Dr. Reddy did not hesitate to agree. After comparing Cæsarean section with the various methods of delivery per vaginam, Dr. Reddy asked, Why advise the most difficult operation when the simpler one satisfied every demand? As to objections to opening the peritoneal cavity, they did not exist under proper conditions. As to hæmorrhage, it was not so great as in an ordinary confinement. Cæsarean section was indicated in hypertrophic elongation of the cervix or with a hard os due to scar tissues. Dr. Reddy had operated in this way for this condition. Cæsarean section was the best mode of delivery in cases of valvular cardiac disease with failing compensation and in congestion of the bases of the lungs. He had performed Cæsarean section for this indication. As soon as the uterus was emptied improvement was noticed and was maintained. Moreover, in this case the patient was sterilised to prevent future pregnancy.

Dr. A. **MCDERMID** (Chicago) stated that he had twice performed Cæsarean section for pelvic deformity, with results favourable to the mother and the child. He had advocated Cæsarean section for placenta prævia, being led to do so by a recent experience in which he almost lost a case of placenta prævia from hæmorrhage, the child dying. Such a case as this might have been saved by the abdominal operation. He regarded Cæsarean section as the best treatment in cases of eclampsia, and agreed with Dr. Reddy in denouncing symphysiotomy.

Dr. **MURDOCH CAMERON** stated that Cæsarean section was quite uncalled for in placenta prævia but was indicated in affections of the cervix or in fibroids, but even here possibly hysterectomy would be better. Cæsarean section might be required in cases of tumours with the soft part blocking the pelvic cavity. In many cases of eclampsia this operation would possibly save life where the os uteri remained undilated.

Dr. **GRIFFITH** agreed with Dr. Reddy in his opinion as to particular cases of placenta prævia requiring Cæsarean section. He was very doubtful as to the advisability of performing Cæsarean section in cases of eclampsia, except possibly in the interests of the child, and he was still more doubtful as to its employment in cases of heart failure.

Dr. **GARDNER** believed that in the list of indications for vaginal Cæsarean section might well be included selected cases of hyperer[illegible] gravidarum in which the symptoms were very urgent, indicating speedy emptying of the uterus. Rapid dilatation was very apt to tear the cervix at the internal os if not at the external os. The clean incision of vaginal Cæsarean section could be carefully adapted and sutured to secure union without cicatricial tissue.

The Value of the Conservative Treatment of the Ovaries.

Dr. Joseph Price (Philadelphia) gave an all-round denunciation of the conservative treatment of the tubes and ovaries, stating that to these operations were due a long train of untoward circumstances which comprised repeated subsequent operations, mental instability, and even insanity.

Dr. Marcy said that the late Dr. Buch of Ontario found on examination of 500 insane women, 100 of whom had been operated upon, 70 returned to health and sanity.

Dr. Floris F. Laurence (Columbus, Ohio) stated that his experience in efforts of conservatism had been unsatisfactory. Three times he had to operate a second time for extra-uterine pregnancy because he did not remove the opposite tube at the first operation. He therefore advocated removal of both tubes whilst operating for extra-uterine pregnancy.

Dr. Manton (Detroit), speaking from ten years' experience, found that the majority of conservative operations were successful. He had reported 100 cases of conservative operations on the appendages without a death. Most of the patients had been under observation for a year; some of them for seven or eight years. In three a subsequent operation was necessary; five others were reported as "doubtful." 15 per cent. subsequently became pregnant.

Dr. Thomas S. Cullen (Baltimore) gave an Epidiascopic Demonstration illustrating the Degenerative Changes in Uterine Myomata, accompanied by a brief pathological dissertation.

Thursday, August 23rd.

The meeting opened by a discussion on

The Appendix Vermiformis in Relation to Pelvic Inflammation.

which was introduced by Dr. T. A. Helme (Manchester). The points on which he invited discussion were the following: 1. That the association of appendicular and pelvic disease is due to contiguity rather than continuity of structure. 2. That the accidental inward direction or pelvic position of the appendix is the chief factor in this association. 3. That the appendix or the pelvic organs may provide the primary source of disease. 4. That appendicitis is a frequent source of dysmenorrhœa and its associated mucous colitis. 5. That association of appendicitis with pelvic disease is the exception and not the rule. 6. That the appendix is not a vestigial structure but a highly differentiated portion of the intestinal tract, and plays an important part in intestinal digestion. 7. That the systematic removal of the appendix during laparotomy for pelvic disease in the absence of evident disease is not justifiable.

The following gentlemen joined in the discussion: Dr. Gilliam (Columbus, Ohio), Dr. Lapthorne Smith (Montreal), Dr. Arnold W. W. Lea (Manchester), Dr. Carstens (Detroit), Dr. Temple (Toronto), Dr. Lockhart (Montreal), Dr. Holmes (Chatham, Ontario), and the President.

Dr. Cuthbert Lockyer (London) spoke on the relationship of appendicitis to pregnancy, its effect on pregnancy, the prognosis of this disease to mother and child, and the treatment of cases in which pregnancy was complicated by appendicitis.

The President gave a lantern demonstration of the Anatomy of Labour which was much appreciated but called for no discussion.

Dr. Murdoch Cameron read a paper on Anti-streptococcic Serum in Puerperal Septicæmia. He advocated the use of this serum for certain types of puerperal fever, more especially those in which there had been no great laceration of the soft parts. With respect to the latter he argued that the serum could not be expected to combat the results of traumatism as well as those of infection.

This paper was not discussed.

Dr. Evans read a paper on the Treatment of Eclampsia, in which he drew attention to Adebohls' operation of renal decapsulation for eclamptic anuria, mentioning successes obtained by means of this operation by Adebohls and others. Helme's lumbar puncture, introduced with the idea of reducing intracranial pressure, had not met with success. The various forms of drug treatment were fully discussed.

Dr. Gilliam described in detail an Operation for Uterine Displacement.

PHYSIOLOGY.

Tuesday, August 21st.

The Section of Physiology opened by holding a joint discussion with the Section of Pathology on

The Part played by the Nucleus in Nutrition.

Professor Adami (Montreal) suggested that the nuclear chromosomes determined the inherited peculiarities of the individual and that by varying amongst themselves they controlled particular conditions. After alluding to the effects of removal of the nucleus the gross and minute changes occurring in the nucleus during the course of cell activities were shortly dealt with, particular attention being drawn to Professor Macallum's researches on the formation of prozymogen from the nuclear chromatin. While in tissues at rest the nuclei underwent shrinkage, they became exceedingly conspicuous in the early stages of cell irritation and in acute degenerations, but in the later stages of cloudy swelling and fatty degeneration they rapidly lost their staining properties and became indistinct. If the nucleus simply contracted or clumped (pyknosis) it might recover its normal appearance, but after complete disappearance of the nuclear chromatin (karyolysis) regeneration of the cell became hopeless. The iron-radicle of nucleo-proteids and also the phosphorus-content facilitated oxidation changes in the nucleus and thereby imparted to the nucleus potentialities superior to those of any ordinary constituent of the cell body. Professor Adami believed that vital phenomena depend ultimately on a special order of molecules which he called biophores, and that the latter were situated in the nucleus, because the vegetative powers of the latter were greater than were those of the cell body. New biophores were supposed to arise under the influence of pre-existing ones by the latter "possessing unsatisfied affinities and attracting side-chains of various ions, simple and compound, from the surrounding media and that the latter became grouped in a manner identical with the grouping present in the pre-existing biophore."

Professor A. B. Macallum laid special stress on the absence of inorganic halogen salts; neither potassium nor chlorine was present within the nuclear membrane, the latter acting as a semi-permeable membrane, impervious to inorganic salts but pervious to organic constituents, which by passing into the nucleus were either aggregated there or were perhaps built up in the nucleus into the nuclear structures.

Dr. Gustav Mann (Oxford) recognised two distinct processes going on normally in the nucleus, one of which resulted in the formation of the basophile nuclear chromatin, while the other gave rise to nucleolar matter. Ordinary somatic cells during active metabolism resembled male cells in possessing a large amount of basophile chromatin and little or no nucleolar matter, while resting cells resembled the ovum in containing a large amount of nucleolar matter and only little chromatin. To him sex meant a loss of balance between these two nuclear functions and fertilisation merely the re-establishment of the balance. During normal metabolic processes induced by feeding with albumin or any of its derivatives down to the amino-acids, in drosera and in the newt nuclear changes resembling the initial stages of true karyokinesis were induced, the number of chromatin segments in drosera being eight, while ordinary dividing cells contain in this plant 16 segments. Attention was drawn to the reduced number of segments in cancer being perhaps only a special phase of ordinary metabolism. Sulphur seemed to be absent in the nucleus and it was possible by the administration of antipyretics mixed with peptone solutions to retard nuclear activity from five minutes to 30 hours.

Professor E. Wace Carlier (Birmingham) believed a nucleus to possess reproductive functions quite apart from vegetative functions and restricted the term nucleole to those bodies containing pyrenin. When the tropho-chromatin decreased during nuclear activity the nucleolus increased in amount, to be cast out from the nucleus at the first opportunity—i.e., so soon as the nucleus took up a food-supply from the lymph. He confirmed Haeker's view that pyrenin was effete material, unavailable for nuclear activity directly, though after resolution in the cytoplasm it might become useful. Zymogen was always derived from the nuclear basophile chromatin and never from the nucleolus.

Dr. E. F. Bashford (London) stated that from the outset of the investigations of the Cancer Research Fund the work had proceeded on the basis that cancer was a cell problem requiring to be approached from the experimental aspect. The problem required to be attacked under conditions more favourable than those obtaining in man. Since the entire vertebrate kingdom had been found to be pervaded by the disease, the processes of cell division had been studied under the favourable, the classical conditions obtaining in the amphibia. The so-called heterotypical mitoses had been found to have no existence in fact. In the case of tumours which could be propagated there was nothing to indicate nuclear fusion or fertilisation. The irregular forms of cell division were apparently subsidiary phenomena. What required explanation was the apparently ceaseless proliferation by normal bipolar mitosis in which the normal number of chromosomes was retained. The cell division was, however, only the terminal phase in the growth of the cell itself and was the most evident expression of the more complex problem of cell nutrition which lay at its basis. Thus stated it was not so much the power of ceaseless proliferation as the ceaseless power the cells possessed of nourishing themselves.

The following papers were then read:—

Proteid Nomenclature.

Professor W. D. **HALLIBURTON'S** paper on this subject formed his Presidential Address to the Section of Physiology and he put before the association the joint deliberations of the Physiological and Chemical Societies of England. It is suggested to substitute for the term "proteid," hitherto used in England, the term "protein," as this word is at present used in America and to a certain extent in Germany (Proteinstoffe).[1] Proteins were divided into: (1) protamines; (2) histones; (3) albumins; (4) globulins; (5) sclero-proteins (instead of the word "albuminoid"), including gelatin, keratin, &c.; (6) phospho-proteins, represented by the vitellin-caseinogen group; and (7) conjugated proteins, in which the protein-molecule is united to a prosthetic group: (*a*) gluco-proteins (e g, mucin), (*b*) nucleo-proteins, and (*c*) chromo-proteins (e.g, hæmoglobin). The products resulting from protein-hydrolysis were divided into: (1) infra-proteins (formerly called acid- and alkali-albumins); (2) proteoses, including albumose, globulose, gelatose, &c.; (3) peptones or substances which could not be salted out from solution, but which still gave the biuret reaction; and (4) polypeptides or compounds resembling peptones, but not giving the biuret reaction. Fibrin being a derivative of fibrinogen and the latter a globulin, it was placed under the globulins. It was finally suggested to continue to use the words: caseinogen, casein, paramyosinogen, and myosinogen.

Tryptic Digestion.

Dr. **DELEZENNE** (Pasteur Institute, Paris) obtained inactive pancreatic juice by the injection of secretin or by catheterising a permanent pancreatic fistula and then rendered it within a few hours as active by the addition of a soluble lime salt as if it had been acted upon by enterokinase. After the juice had once been rendered active the calcium could be completely removed by means of sodium oxalate without the digesting power suffering in the least. If alkali carbonates and phosphates were removed from the pancreatic juice by means of dialysis, extremely minute quantities of a lime salt were sufficient for activating purposes and lime seemed to be a specific activator inasmuch as barium, strontium, and magnesium had no, or only a very slight, action, which latter might be accounted for by traces of lime salts present in the juice itself.

Dr. S. P. **BEEBE** (Cornell University, New York), continuing his work on

Nucleo-proteid Immunity,

found it much more difficult to obtain highly active anti sera to nucleo-proteids than to albumins or globulins, for animals would bear after repeated inoculations only from three to four times the initial dose, especially if thyroid proteids be taken. Highly active anti-nucleo-proteid sera showed in a test tube a specific precipitin reaction, except they be in very high concentrations; they produced very quickly a complete agglutination if very fine fragments of the same kind of organ which was originally used in their preparation be suspended in salt solution. Thus an active anti-thyroid serum would agglutinate in concentrations of 1 in 2 up to 1 in 5 a thyroid emulsion in one second, while it caused no agglutination of muscle, kidney, liver, spleen, or lymph-gland emulsions in half an hour at the same concentration. Anti-nucleo proteid sera also possessed *in vitro* weak hæmagglutinative and hæmolytic properties (which latter were quite distinct from the precipitin and agglutinin reactions), but these hæmolytic reactions did not occur *in vivo*, there being even an increase of 25 per cent. in the hæmoglobin and in the number of erythrocytes. Inoculation of animals showed an almost complete specificity.

Dr. H. E. **ROAF** (Liverpool) found minute traces of acid to inhibit the growth of sea-urchin's eggs, while traces of alkali favoured the rapidity of growth, but were likely to give rise to irregularities in the size and shape of the cells.

Professor **KEMP** (Champaign, Illinois) said that blood platelets contained nucleo-proteid material. They increased at high altitudes even more markedly than the red corpuscles. If the blood plates increased in number during treatment of a severe case of anæmia the diagnosis of pernicious anæmia was excluded and the prognosis was good; in purpura hæmorrhagica the plates were greatly reduced in number.

WEDNESDAY, AUGUST 22ND.

A joint discussion on Over-nutrition and Under-nutrition, with Special Reference to Proteid Metabolism, was held with the Section of Medicine, Sir **THOMAS BARLOW** being in the chair. This will be found in the report of the Section of Medicine (p. 729).

The Metabolism of Kreatin and Kreatinin.

Dr. **FOLIN** (Waverley, Massachusetts) said that kreatin was not the immediate precursor of the kreatinin appearing in the urine, for given in moderate quantities with a low nitrogen diet (starch and cream) it was not eliminated at all; given in large quantities (from five to six grains) with a low nitrogen diet about one grain was eliminated unchanged, while if it be given along with food rich in proteid matter 50 per cent. was excreted unchanged in 24 hours.

Chemical and Physiological Studies on Growth.

Dr. **MENDEL** (Yale University) said that the purin compounds formed in a developing egg were guanin and adenin and mere traces of hypoxanthin. There were always present a number of enzymes engaged in transforming purin-containing material, such as nucleases, amidases, oxidases, uricolytic enzymes, &c. The power of destroying uric acid was but feebly developed in the embryo liver, while it was very marked in the adult liver. Pentose radicles were formed *pari passu* with the purin radicles in developing eggs.

Professor B. **MOORE**, Dr. **ROAF**, and Dr. **WHITLEY** (Liverpool) stated that hydrogen-ions diminished while hydroxyl-ions tended to increase cell-division. Neutral salts showed no toxic effect so long as their osmotic pressure did not almost equal that of the internal fluids. Barium and ammonium were, however, toxic. Phosphates in low concentration favoured growth while in high concentrations they retarded growth.

Dr. **REID HUNT** and Dr. B. **DE M. TAVEAU** (Washington) recorded that after introducing various fatty acid radicles into the ethy-oxy group of choline these new compounds were tested physiologically. The acetyl derivative was nearly as powerful as adrenalin but in the opposite direction; it was 1000 times more powerful than choline itself, causing marked fall of blood pressure. Introducing an aromatic radicle gave rise to compounds which raise the blood pressure both before and after atropine. One cubic centimetre of a solution of 1 in 25,000 of phenyl-propionyl-choline chloride would cause a rise of blood pressure and marked slowing of the heart.

Structure and Functions of the Amœba.

Professor C. F. **HODGE** (Worcester, Mass.) and Professor M. F. **DUNCAN** (Clark University, U S.A) made a communication in which they said that the aim in view was the elucidation of how elementary tissues had become evolved. The neuro-muscular functions in amœba were bound up with a system of fibres which were very delicate at the periphery of the cell and much coarser in the middle. The ectosarc and endosarc of living cells disappeared after fixation. The functions of digestion, assimilation, and growth were in the amœba represented as follows: the zymogen-granules were intranuclear but during digestion passed out into the food vacuoles and there digest such food materials as paramœcia, &c. The contractile vacuoles helped to bring about a circulation of the cell juices and at the same time helped respiration and excretion.

---

[1] Emil Fischer has now definitely adopted this expression.

PATHOLOGY AND BACTERIOLOGY.

TUESDAY, AUGUST 21ST.

The programme of the Section of Pathology, officially termed the Section of Pathology and Bacteriology, after separating from the Section of Physiology commenced with a paper by Dr. R. M. **PEARCE** and Dr. H. C. **JACKSON** (Bender Hygiene Laboratory, Albany, New York) entitled

Concerning the Production of Somatogenic Cytotoxins by the Injection of Nucleo-proteids.

The experiments made were the immunisation of rabbits to nucleo proteids by the use of washed kidney and pancreas of the dog. The resulting serum was injected into dogs intravenously in doses of two cubic centimetres per kilogramme of body weight. As a control test a serum prepared by injecting cows' pancreas was used. In order to limit the problem sharply attempts were made to immunise with nucleic acids of kidney and pancreas respectively. The resulting sera were found to cause a general disturbance most marked in the kidney. These lesions were therefore the result of a toxic substance having a more or less general action but with especial effect on the chief excretory organ, the kidney. They could not be said to be specific in their action.

The discussion was continued by Professor A. S. **WARTHIN** (Ann Arbor University). He considered that the facts stated as apparent proof of the specificity of the serum prepared by Dr. Beebe were not sufficient proof that such a serum was specific for the following reasons. An identical delayed toxic reaction was shown in the kidneys of small animals that had been exposed to Roentgen rays for several hours. When examined immediately after the irradiation very slight and transitory changes were found in the kidneys. After a number of days albuminuria developed and a marked condition of cloudy swelling was found in the kidneys. This delayed toxic action might be explained as resulting from the products of proteid disintegration caused by the irradiation. Might not the delayed renal action produced by Dr. Beebe's serum be similarly explained as the result of poisons formed from the action of the serum? Experiments in his laboratory by Dr. Woltmann tended wholly to confirm Dr. Pearce's work. They could produce no specific sera; all were hæmolytic, lymphotoxic, myelotoxic, nephrotoxic, &c., and no specific histological changes could be produced. He agreed with Dr. Beebe as to the variability of reaction shown by different animals.

Dr. W. W. **FORD** (Johns Hopkins University) contributed a paper entitled

A Consideration of the Poisons present in Amanita Phalloides.

Dr. Ford described the toxicity of the poisonous fungus, the white or deadly amanita, which had caused 300 fatalities from its consumption. With Professor Abel of the Johns Hopkins Medical School, a chemical study of the fungus was carried out. In 1891 it had been discovered that aqueous and saline extracts of the fungus were powerfully hæmolytic, dissolving a variety of corpuscles in great dilution; the agent was considered to be a toxalbumin, this active principle being known as phallin. As, however, the toxicity of these fungi was not destroyed by cooking, other substances than phallin, which was destroyed at 70° C., must be present. Thus, heating extracts of the fungus to 70° and to 80°, destroying their hæmolytic properties and digesting them with pepsin and pancreatin, left behind a highly toxic substance which killed animals rapidly and produced a different pathological picture post mortem. Moreover, Kobert in a later paper stated that there was a third toxic substance present in addition to toxalbumin and alkaloid. In Dr. Ford's work the fungi were identified as Amanita phalloides in the fresh state and collected in the Blue Ridge Mountains of Pennsylvania and their juices obtained in large amounts and evaporated. The precipitate obtained by alcohol was found to contain the hæmolysin; the clear filtrate contained the amanita toxin. The Amanita rubescens contained a powerful hæmolysin for a variety of blood corpuscles, apparently identical with that of the deadly amanita. This furnished the final proof that the hæmolytic substance described by Kobert had nothing to do with the intoxications in man. The lesions produced by ingestion of the fungi were to be attributed, as their pathological character suggested, entirely to the amanita toxin, which was regarded as the active principle of the plant.

Dr. E. F. **BASHFORD** (London) stated that if Dr. Ford had obtained an active immunity to glucosides it was the first occasion and of fundamental importance as linking the proteids and carbohydrates proper.

Dr. **FORD**, in reply, stated that animals had been successfully immunised to extracts of Amanita phalloides, which contained poisonous glucosides and in some cases to these glucosides in association with proteid and free from proteid.

Professor W. H. **MAINWARING** (Indiana University) dealt with

The Application of Physical Chemistry to Serum Pathology,

summing up two years' work on the chemical composition of antitoxic and bactericidal sera by physico-chemical methods in answer to the papers of Arrhenius and Madsen which were published in 1904.[1] The problem was attacked from the aspect of the partition coefficient and the reversible reactions, two physico-chemical laws the application of which had been attempted to serum phenomena; the illustrations were expressed in mathematical terms and numerous diagrams were shown.

Professor R. **MUIR** (Glasgow) with Dr. W. B. M. **MARTIN** (Glasgow) contributed a paper

On the Combining Properties of Opsonins of Normal Serum.

The three chief varieties of immune bodies (amboceptors)—viz., those obtained by the injection of (*a*) red corpuscles, (*b*) serum, and (*c*) bacteria respectively—were treated and it was found that in each case the combination of receptor + immune body removed the opsonin of normal serum as tested by an emulsion of staphylococcus aureus. It was shown that a bacterium treated with immune body took up more of the normal opsonin than the same bacterium untreated. It was intended next to test whether the comparatively thermostable opsonin which might be present in an immune serum could be removed by the methods of absorption employed above. In this way information might be obtained as to the classes of opsonins so far as their combining relationships were concerned.

Professor G. SIMS **WOODHEAD** (Cambridge) was glad to merge his paper in that of Professor Muir as he had only one or two points to raise. He had found opsonins corresponding to complements in cows' milk and also opsonins of a somewhat different character the results of the infection of tubercle.

Dr. G. W. **ROSS** (Toronto) said that the opsonic power of the blood of newly born children to the tubercle bacillus was about one-half that of the mother, whilst it was about the same in each case to the staphylococcus pyogenes. The practical importance of these observations concerned infant feeding and whether or not mother's milk was essential in remedying this deficiency of tuberculo-opsonic power.

WEDNESDAY, AUGUST 22ND.

Professor R. F. C. **LEITH** (Birmingham) presided.

Dr. F. J. **SMITH** (London) contributed a paper with Dr. C. **MILLER** (London) on

Gastric Erosions,

in which he maintained that the first stage in probably all cases of acute gastritis or gastric ulcer was inflammation of the small collections of lymphoid tissue in the submucous coat of the stomach. Subsequent events—e.g., hæmorrhage, gross ulcer (acute or chronic), perforation, &c.—depended entirely upon the relative power of the inflammation factors *versus* the reparative powers of the mucous membrane of the stomach.

A discussion on the

Etiology and Life-history of Malignant New Growth

was opened by Dr. G. H. A. **CLOWES** (New York State Cancer Laboratory, Buffalo), in a paper on Experimental Studies in Mouse Tumours. Most important results were obtained by the study of the action of chemical and physical agents on mouse tumours and evidence was detailed of spontaneous recovery from, and immunity against, mouse tumours. Data were presented regarding experiments carried out by Dr. Clowes and Professor Gaylord, the essential points brought out being as follows. Three main types of tumour had been employed: (1) "Jensen," showing 30 per cent. of successful inoculations with slow development and over 20 per cent. of spontaneous recoveries; (2) "Brooklyn" tumour, giving 90 per cent. yield, with rapid development and only

---

[1] Brit. Med. Jour., vol. ii., 1904, p. 565.

5 per cent. recoveries; and (3) "Spingfield" tumour, which only gave tumours at start by incubation before transplantation and 30 per cent. recoveries. It was shown that tumour cells were far more resistant to chemicals than bacteria, withstanding $\frac{N}{200}$ KCN and $HgCl_2$ at 1 in 2500. Proof of immunity was afforded by the following points:—(1) Spontaneous recovery from true tumours occurs; (2) spontaneous recovery cases are not re-inoculable; (3) there are reduced yields on second and third inoculations; (4) mice with growing tumours fail to take on second inoculation at a different point in the body; and (5) action of serum of recovered mouse on small tumours and on cancer cells. It was shown that immunity was not conferred by injection of tumour cells killed by heat or by chemicals or by nucleo-proteids extracted from tumours. Ehrlich's recent theory of cancer was discussed and Dr. Clowes showed that the results of the later work of the New York Laboratory harmonised better with the theory of a stimulating virus. These results could not for the present be applied to human beings.

Dr. BASHFORD described the work of the Imperial Cancer Research Fund. In the mouse 28 spontaneous tumours had been transplanted with 25 per cent. success. The parenchyma of the tumour was the only part that grew on transplantation; the stroma never. Dr. Bashford dwelt upon the absence of any sharp distinction between expansive and infiltrative, or, in other words, simple and malignant growths. An investigation into the statistics of cancer incidence with the Registrar-General showed that there were no increase of cancer and no evidence of endemicity in cancer.

Professor H. R. GAYLORD (New York State Cancer Laboratory) contributed a valuable paper on the evidences that infected cages were the source of spontaneous cancer developing among small caged animals. He found in one year three cases of sarcoma of the rat in one cage in which had been previously kept rats with transplanted sarcoma. There were eight rats exposed in the cage with three positive results. He located one cage in the establishment of a dealer from which in three years 66 spontaneous mouse tumours were found. During this time the stock was completely changed. Again, a second dealer found eight or nine cases of cancer in groups in separate small cages.

Professor EWING (New York) and Dr. S. P. BEEBE gave a preliminary report of a study of the action of salt solution, nucleo-proteid antiserum, susceptible blood, and immune blood upon the cells of the infectious lymphosarcoma of dogs. In some experiments the fluids were saturated with oxygen, in others with nitrogen, and finally in some the blood was changed every 12 hours. The best preservation of cells was obtained by charging the blood every 12 hours and saturating with oxygen, by which means a peripheral layer of cells about the tumour nodule was well preserved for at least 96 hours. Susceptible blood formed a better preservative than immune blood. In salt solution the cells rapidly recovered. Atmospheres of nitrogen were comparatively unfavourable. The former tests were not concluded.

Professor SIMS WOODHEAD regretted that he had been unavoidably prevented from hearing the earlier papers on the subject and expressed diffidence in continuing the discussion. He was so much interested, however, in the later papers that he would make no further apology for intervening at this stage. The points that impressed him most were, first, the promise of further results from the fact that so large an amount of spontaneous tumour growth in mice could so easily be obtained, and, second, the importance of the work founded on the side-chain theory, as expounded by Ehrlich and his school. So far most of their efforts had been directed to clearing the ground and of removing many of those hampering traditions that cling round the question of cancer growth. It was hoped that greater attention might thus be centred on the real and prime factors in this very complex problem. With a large amount of material, during the collection of which some of the factors in the question might be solved, many of those questions as to the difference or likeness of structure and function between cancer cells and normal epithelial cells of various types might be gradually attacked. The specificity of antibodies and the relation of these antibodies to the cells might give us light as to the specificity of the cells. Minute differences in albumins in blood gave specific differences in the form of the antibodies and it remained for them to see whether there might not be equally minute but specific differences between cancer cells and normal epithelial cells. Along these lines they might through the study of function learn something of structure, and of structure learn something of the nature of the altered function of cancer cells.

Professor WILLIAM H WELCH expressed great satisfaction in the opportunity of hearing these important subjects presented by those actually engaged in the researches on cancer. He expressed the view that the extraordinary observations reported by Dr. Clowes regarding the insusceptibility of cancer cells from tumours of mice to the action of strong germicides, such as corrosive sublimate, the cyanides, &c., could be explained only on the assumption that in some way the germicide was prevented from coming into actual contact with the living substance of the cells, and he referred to his observations on the influence of sublimate in cutaneous disinfection where this explanation applied. Professor Welch called attention to the differences between spontaneous tumours of mice and of dogs, the latter being often complex and even teratomatous. As to the question of the unicentric origin of cancer in Ribbert's sense, the examination of beginning adeno carcinomata of the uterus in scrapings showed often cancerous metamorphosis of groups of cells over comparatively wide areas.

Dr. F. G. BUSHNELL (Brighton) summed up briefly his contribution to the discussion from his observations as a pathologist to a general hospital and expressed his appreciation of the work of those who had spoken and were devoting their lives to cancer research. One feature in the histological examination of normal and abnormal tissues stood out—viz., the continuity in structure which linked up normal and abnormal growth. An analogous condition was seen in metaplasia which occurred in carcinoma of the cervix uteri, in gastric carcinoma, and elsewhere. Thus a study of cancer resolved itself into a study of the laws of growth. This could be carried out from the point of view of (1) structure and of (2) function in biochemical terms. Personally Dr. Bushnell had never yet found one single feature by which the departure of the cell from its specific maintenance of form and activities was to be detected. Even heterotype mitoses which he carefully observed and recorded in 1902 were not essential to cancer structure. As illustrations of the linking-up of tissues were given that of the young trophoblast (chorion-epithelium) which had a striking power of growth and in the early stages of the imbedding of the ovum had physiological relationships which were destructive to the boundary zone. Again, hydatid mole was an excessive proliferation of both layers of the chorionic epithelium. Malignant mole showed a little more overgrowth of epithelium, some infiltration of the decidua and invasion of vessels, but histological distinction between simple and malignant mole might be absolutely impossible. The pure chorio epithelioma might be made up entirely of epithelial tissue and might resemble a "mole" in this respect The condition was an exaggeration of that of the normal attachment of villi to the decidua in the young placenta. Examples of simple growth becoming malignant were adduced, such as adenoma mammæ becoming carcinoma; melanotic papilloma cutis giving rise to diffuse malignant growth of liver; of a "callus" tumour of the humerus of osteoid tissue following fracture becoming a low type of sarcoma; of multilocular ovarian cysts derived from the follicular epithelium or from germinal cell down-growths in the ovary becoming malignant by an alteration of the distribution and arrangement of its epithelium cells; of fibromyoma uteri which became sarcomatous; and the various cell seclusions and teratomata which gave rise to neoplasms. The study of the functions and activities of cell life was indicated in cancer research. Granulation tissue could exhibit an erosive or malignant character of low or even high type, but it seemed usually of a purposeful though sometimes of an apparently useless function. When the biochemical changes which resulted in granulation tissue were known they might expect to be on the line of the origin of malignant new growth. It was thus he hoped to work.

Professor WARTHIN gave a most valuable demonstration of the Leucoblastomata, illustrated by lantern slides, in which the origin of these leukæmic conditions was discussed and the deposits in various viscera were regarded as metastases from an original neoplasm.

STATE MEDICINE.

TUESDAY, AUGUST 21ST.

The President of this section was Dr. C. F. MONTIZAMBERT (Ottawa), who welcomed the members present in a few suitable words. The proceedings of the day were confined to a discussion on the questions connected with the prevention of tuberculosis.

Dr. SAMUEL DIXON, Health Commissioner of the Commonwealth of Philadelphia, U.S.A., read a paper entitled

Phthisis Prevention,

in which he detailed a series of experiments extending over the past 17 years in research work: the efforts to find a bacillus which could produce a suitable antitoxin to tuberculosis had succeeded so far as animals were concerned. He stated that the following propositions had been used as his guide: 1. That it was possible that by a thorough filtering of bacilli obtained from tuberculous material a filtrate might be obtained and attenuated so that by systematic inoculations a change might be produced in living animal tissues that would enable them to resist virulent tubercle bacilli. 2. To bring about a chemical or physical change in living tissues that might resist tuberculosis it was possible that inoculations with the bacillus would have to be made, yet before this could be done the power of the virulent bacilli would have to be diminished, otherwise the result would be most disastrous. The dangers which must inevitably result from the direct introduction of the bacillus into the human body led him to labour in the direction of trying to obtain the active principle which would produce immunity. He then proceeded to discuss the relationship between the tuberculous diathesis and nitrogenous metabolism, pointing out that it was confidently asserted that the victims of gout presented a remarkable immunity from tuberculosis, and from this he deduced a possible treatment based upon the introduction into the system of substances containing taurin, creatin, urea, and the like, and more especially the use of a recently discovered drug of vegetable origin called thiosinamin, and further the possibility of establishing a lithæmic habit involving excessive assimilation and metabolism of proteid substances together with increased oxygenation to antagonise the action of the tuberculous diathesis involving deficient assimilation and decreased oxygenation. He then alluded to the work done at the Henry Phipps Institute of Philadelphia, which had been founded for the study, treatment, and prevention of tuberculosis and of the production by men of science of a modified tuberculin. Reference was further made to the experiments of Ravenel, Marmorek, and Cantacuzene with bacilli from dead animals. It was upon the lines thus laid down as a basis for future experimenters that he proposed to continue his search for an antitoxin to tuberculosis and with the magnificent assistance rendered by the State of Philadelphia he was hoping for good results.

The next paper was read by Dr. ROBERTS, medical officer of health of Hamilton, Ontario, a manufacturing town of about 70,000 inhabitants. Dr. Roberts approached the subject under the following headings: (1) responsibility of federal authorities; (2) responsibility of provincial legislatures; (3) responsibility of municipalities; and (4) the individual's responsibility. He based his paper upon the assumption that pulmonary tuberculosis was not an incurable disease and that it could by proper measures be eradicated. He further went on to estimate the number of sufferers in Canada at 40,000 and the annual financial loss to the country at $8,000,000. As regarded State measures he congratulated the province of Ontario on having made a grant of 40 per cent. of the total cost of erecting any consumptive sanatorium and took credit to his own town of Hamilton for having taken the initiative in claiming the grant; he strongly advocated the addition to the Cabinet of a Minister of Public Health in every province of the Dominion. There was unfortunately now a new disease which might be called "phthisiphobia" arising among the public which consisted in a fear that it was not possible to check pulmonary tuberculosis. Such a scare could not be justified by any evidence. It was one of the most pitiable bogies he had ever met with. Dr. Roberts emphatically pointed out that the prevention and eradication of consumption constituted not merely a problem for medical men, but that it involved nearly every social and economical problem of modern life which was awaiting solution. In concluding his paper he spoke at considerable length of his own experience in Hamilton and of the difficulties which he had experienced in obtaining any satisfactory notification of cases of tuberculosis. He fully agreed that the measures which would cure pulmonary tuberculosis would also tend to its prevention and spoke of the need for better homes for the working man, for more holidays of a regular character, and for the eight hours' day.

Dr. GILCHRIST (Nice) then read a paper dealing with

Certain Analogies between Influenza and Pulmonary Tuberculosis,

based upon certain theses which he put forward as follows: (1) both diseases had prevailed in epidemic and endemic forms although in different surroundings; (2) both affected principally the organs of respiration; (3) both diseases were highly infectious and a single attack did not confer immunity but on the contrary rather predisposed to a second invasion; and (4) both diseases showed by rheumatic symptoms and involved by extension the nervous system generally.

Dr. PROBST (Ohio) next dealt with some of

The Disputed Questions in connexion with Pulmonary Tuberculosis

and spoke of the varied phases of its causation. The disagreement by authorities such as Behring and Koch upon the all-important question of infection by ingestion and the dangers more especially of infected milk were dealt with and Dr. Probst then turned to the dangers of bad or tuberculous meat as illustrated by the Chicago revelations. The public were now beginning to believe that pulmonary tuberculosis, instead of being hereditary, was really an infectious disease and had begun to demand almost impossible measures. The exclusion of the known consumptive from the school, the church, the theatre, the concert, the tram-car, the railway-car, and, indeed, from any public assembly, seemed to be a severe violation of personal rights and could not be supported by the medical profession as essential. They ought, however, to insist upon such measures as would prevent dried sputum being thrown upon the wings of every wind and upon the observance of certain simple rules and hygienic conditions. The part played by alcohol in promoting the activity and spread of tuberculosis was still to be ascertained and as there was a vast difference between the use of alcohol and alcoholism there was also the necessity for considerable differentiation according to the status of the patient. It had never been proved that alcohol in and of itself was responsible for the production of tuberculosis. The marked decrease of tuberculosis in civilised countries was to be viewed with satisfaction and most people would ascribe this to the generally improved hygienic conditions, but, on the other hand, this improvement, noted in England, in France, in Germany, and in America, did not extend to Hungary and Austria. In the different countries attention was being paid to different points and it was probable that even if the medical profession had at its disposal $1,000,000 for the prevention of tuberculosis it would know how to spend this sum. In matters of treatment it was the same and no sure course could be agreed upon. The best form of sanatorium, the need for sleeping out of doors in all weathers and all climates, the provision of amusements and even chapels, forced feeding, and the use of alcohol, were all points of disagreement. In conclusion, Dr. Probst pleaded for a better general system of home treatment for consumptive patients.

Dr. HOMAN (St. Louis) presented a short paper on

The Dust Problem as shown in Public Buildings and Private Houses.

Dusting consisted in the mere displacement of dust from one surface to another and not in its removal. He advocated compulsory cleaning by vacuum systems and the more extended use of the damp cloth.

This concluded the reading of papers and a spirited discussion followed.

Dr. GILCHRIST suggested that Dr. Dixon in his remarks upon the relation of gout to pulmonary tuberculosis had mistaken effect for cause. To load a stomach already weakened by a disease which demineralised the whole system was simply to produce an acute dyspepsia. In such cases the primary need was to restore the chlorides of the body by the judicious administration of hydrochloric acid and not to give an excess of nitrogenous foods. He relied more upon the chemistry of the disease and quoted the theories of Gautrelet as to the value of systematic urinary examinations.

Dr. PROBST said that he was almost inclined to think that the discovery of a cure for pulmonary tuberculosis would not be a good thing. People could only be induced to cease the habitual violation of the laws of health by being penalised and in this way the disease had its uses. Cure and prevention of necessity went hand in hand and the real need in both was for healthy houses and sanitary surroundings.

Dr. J. BARR STEVENS (Renfrew) related some personal experiences of the value of fresh-air treatment in his own family and explained the methods by which the lessons of prevention were being taught in Renfrew in a popular form.

Professor JOHN GLAISTER (Glasgow) pointed out that the Local Government Board for Scotland had now officially recognised phthisis pulmonalis as an infectious disease and that it was open to local authorities in Scotland to adopt the same measures of notification, isolation, and disinfection, as in the case of other infectious diseases. To some extent this had been done and further efforts had been to educate people by lectures and leaflets. It was also needed that in populous cities more attention should be given to the prevention of smoke and dust nuisances, both of which were the cause of much respiratory disease.

Dr. WOODWARD of the United States Marine Hospital Service gave an interesting description of the Hospital for Consumptives established by the State at Fort Stanton, New Mexico, and of the precautions adopted for the transit of the patients. So far excellent results had been achieved.

The discussion was closed with a most interesting personal reminiscence by Dr. J. GROVES (Isle of Wight) who had himself been a consumptive and who advocated the use of single tents and camps in preference to sanatoriums, which, though costly and very magnificent, did not so fully achieve an open-air treatment. To educate one patient and to cure him was to send out a health missioner to preach the gospel of fresh air and to announce that pulmonary tuberculosis was not wholly incurable. If all consumptives could be taught to lead suitable lives the gain to themselves and the community would be very great.

WEDNESDAY, AUGUST 22ND.

The Protection and Filtration of Water-supplies.

The first contribution to the subject was a paper by Dr. ROBINSON, who holds the position of health officer at Guelph, Ontario. He commenced by giving an outline of the principal factors common to all water problems. The essential points in connexion with every water-supply were continuous sanitary supervision from the moment of installation, regular and periodic examinations of the supply, and suitable treatment of all waters which were, or were likely to become, dangerous. The only practical method of artificial purification upon which reliance could be placed was filtration where large bodies of water were used. In England a filter-bed was, in fact, a closed reservoir suitably underdrained and filled to a height of five or six feet with suitable filtering material. The water flowed evenly and slowly over the sandy surface, leaving most of its sediment and suspended matter on the top. This formed a coating called "Schmutzdeck," which contained not only suspended matter but a gelatinous substance produced by bacterial action. Sand filters, however well constructed when newly installed, required cleaning at frequent intervals, otherwise they would become impervious. A usual rate of filtration would be from two to two and a half million gallons per acre per day, and filters of this kind would cost in Canada about 60,000 dollars per acre, smaller filters costing more in proportion than large ones. The mechanical filter was mainly of American origin and required the addition of a small quantity of some coagulant—e.g., aluminium sulphate—before the water reached the filter. This formed a white jelly-like precipitate in which suspended matters and bacteria were alike entangled. The rate of filtration was as great as 100,000,000 gallons per acre per day and the cost might be estimated at 20,000 dollars per million gallons plus a cost in operating of about seven dollars per million. He considered that either system would be efficient in removing both chemical and bacteriological impurities and that with the American system no less than 98 per cent. of the bacteria could be eliminated, besides which there was greater efficiency in removing colour and turbidity.

In the absence of Dr. HILL (Minneapolis) his paper was read by Dr. WESBROOK, the director of the public laboratories of Minnesota. The paper dealt with the essentials of pure water-supplies and the responsibilities in the matter of every municipality. Dr. Hill urged that it was the duty of the board of health not merely to keep itself informed as to the chemical and bacteriological condition of the water but to advertise the information it thus acquired. The dangers of propagating typhoid fever by means of water were discussed and the measures to be taken in stamping out an epidemic of typhoid fever were very fully outlined. Dr. Hill urged that it was quite as much the duty of the water authorities to supply pure water as it was that of the milkman to supply pure milk and that they with the fraudulent milkseller should be equally liable to penalties.

Mr. HOLTON, secretary to the Vermont board of health, then read a brief paper in which he alluded to the mysterious pollution of artesian wells which might be due to a cause quite half a dozen miles from the boring. He considered that it was practically hopeless to prevent the pollution of the sources of supply and that the only safeguard lay in filtration. The reason of this was that up to the present no law had ever been put into operation to restrain municipal authorities from polluting the streams. In systems of filtration he recommended the mechanical filter for small municipalities as not interfering with the fire service and as being more economical; the prevalence of waste in the use of water was much to be regretted and ought be checked. Since the very life of the citizens depended upon a pure water-supply it was most necessary to supervise the sewerage schemes of all towns and also to keep a careful watch over the working of the filter. Typhoid fever was not the only disease due to water and there were many cases of kidney trouble, &c., arising from the same source.

Professor STARKEY (McGill University, Montreal) gave a most interesting account of the experiments which he had carried out during the last four years with regard to the rivers St. Lawrence and Ottawa, and especially to a portion of the Ottawa at West Mount, Montreal. So far none of these waters would be condemned upon a chemical analysis and he could not even say that bacteriologically they were an actual source of danger. But it could not be denied that the bacteriological evidence of pollution as shown by the increase in the number of colonies per cubic centimetre was steadily on the increase, and this increase constituted a potential danger. He had no wish to be considered an alarmist but it must be evident that this was a condition which could not be overlooked. He then made reference to the epidemic at Winnipeg which arose from water that a few years before had been no worse than was that of the Ottawa or of the St. Lawrence of to-day. Sewage disposal must be reformed and efficient filtration enforced or else such a case as the Ottawa water off West Mount would soon become a serious menace to public health and other places would follow.

During the discussion which followed these papers Professor GLAISTER spoke at some length of the necessity for water-supplies being in the hands of the municipality and not, as too often was the case, the property of companies working for a profit. He was glad to say that water companies were rare in Scotland and now many of the large towns, London excepted, were providing new and pure municipal supplies at immense cost and from great distances. They were insuring the purity of their sources of supply either by purchasing the gathering grounds outright or by acquiring such rights over them as would enable their officers to enter and examine all sources of supply. As to filtration there was one difficulty: it did not remove the discolouration of peaty and moorland waters. The three essentials in protecting a water-supply therefore were: (1) the purity of gathering grounds when acquired; (2) the periodical inspection of sources to detect and prevent fresh pollution; and (3) the regular chemical and bacteriological examination of the supply.

Dr. OLDRIGHT (Toronto) alluded to the freedom of the Muskoka Lakes district from any traces of epidemic disease and hoped that all would use their influence to keep up the preventive measures for restraining pollution which now existed.

Dr. PROBST pointed out that while all States possessed laws restraining the pollution of rivers they were not uniformly enforced. In Ohio the board of health had recently been upheld in an attempt to prevent a city from using a certain water-supply. They must, however, remember that water was not the only cause of typhoid fever.

Dr. T. G. NASMYTH (Cupar, Fife) briefly alluded to the duties of the medical officer of health where river pollution was concerned and regretted that public authorities were hampered by a fear of affecting trade or injuring manufacturing interests.

Dr. BRYCE (Ottawa) said that in his official position he had inspected over 100 water-supplies; he considered that the death-rate from typhoid fever was low in Ontario and this was largely due to the supervision of the sources of water-supply. There was, however, a need to educate people in better methods of disposing of sewage and refuse.

After Dr. HOMAN had spoken on the legal aspects of the question as illustrated in the dispute between Chicago and St. Louis, the debate was closed by Dr. GROVES in a few words contrasting the conditions prevailing in Canada and in England. He pointed out the powers of the Local Government Board with regard to water-supplies and emphasised the necessity for going back to the primary rock source of supply, which must be protected from pollution.

PSYCHOLOGY.

TUESDAY, AUGUST 21ST.

Dr. A. R. DIEFENDORF (Connecticut) communicated a paper on

The Etiology of General Paralysis

which, in the absence of the author, was read by Dr. A. T. HOBBS (Guelph). Dr. Diefendorf's material was from 172 cases which occurred during seven years (1898 to 1905) in the Connecticut asylum. In this period the percentage of general paralysis to all other forms of insanity did not show any tendency to rise and ranged between 7·8 and 5·4 per cent. per annum. He found, however, that there was a distinct tendency for the number of female general paralytics to increase. He discussed statistically the more specific causative factors and assigned the greatest importance to syphilis, yet he considered that alcohol might be as capable of producing general paralysis as syphilis.

The PRESIDENT (Dr. W. J. MICKLE, London) then opened a discussion on

General Paralysis,

dealing with the delimitation of the disease under the chief headings of (1) symptoms; (2) morbid anatomy; and (3) pathogenetic relations.

Dr. W. ALDREN TURNER (London) referred to the etiological connexion between general paralysis and tabes dorsalis and stated that in his opinion the evidence pointed to syphilis as the great predisposing factor in both disorders, but also suggested that an exciting cause was to be sought for, such as trauma, alcoholism, nervous stress, or possibly, in view of Ford Robertson's researches, intestinal auto-intoxication.

Dr. L. H. METTLER (Chicago) believed that the variable prognosis held in regard to the ultimate outcome of general paralysis was due to the emphasis laid respectively upon the clinical manifestations or upon the pathological findings. He held that general paralysis was another phase pathologically of the tabetic process.

Dr. J. D. O'BRIEN (Massillon) referred to some experimental work which he had undertaken with reference to the bacteriology of general paralysis on the lines of the views formulated by Ford Robertson. He obtained an organism similar to the Klebs-Löffler bacillus in over 95 per cent. of general paralytics, but in other types of insanity in only 2 per cent. Animals inoculated had developed congestive seizures and other physical symptoms of the disease, and post-mortem examinations have revealed lesions similar to those seen in early general paralysis.

Dr. A. T. SCHOFIELD (London) read a short paper entitled "The New Psychology."

WEDNESDAY, AUGUST 22ND.

Dr. C. K. MILLS (Philadelphia) read a paper on

Cerebral Localisation in the Study of Psychiatry.

He started with a brief review of the literature and of personal observations concerning hallucinations and delusions, taking the view that these symptoms, regarded from the psychiatrical standpoint, never occurred as the result of the irritation, instability, or destruction, or combination of these, caused by lesions limited to cortical areas or centres of the senses conditioning these phenomena. The phenomena when they rise to the plane of insane hallucinations require for their explanation disruption or dissociation of the mechanisms which associate not only those centres with each other but with other parts of the brain. He reviewed many personal cases of coarse focal disease and then took up the question of diffuse destructive degenerative disease, such as cerebral syphilis and progressive pre-senile dementia and general paralysis, in which hallucinations and other genuine insane phenomena were present. He referred also to the observations of K. Schaffer and Sœmmerling on lesions of general paralysis in their relations to association and projection areas, and to personal observations on the anatomical and morphological peculiarities of the cerebral surface in cases of paranoia and in low types of brain generally. Here the preponderance of arrest and aberration was most noticeable in the great association regions. He suggested the classification of insanity on the bases of (1) structural arrest or embryonal apotentiality; (2) course and prognosis, especially as conditioned by developmental periods; and (3) election of cerebral mechanisms by exciting causes, bacteriological or toxic.

Dr. JOHN TURNER (Brentwood, Essex) gave a Lantern Demonstration illustrating his findings in the

Central Nervous System of Epileptics.

He held that this disease occurred in persons with a defectively developed nervous system, in whom there was a morbid condition of the blood which showed a special tendency to intravascular clotting, and that the immediate cause of the fits (either *grand* or *petit mal*) was sudden stasis of the blood stream, resulting from the blocking of cerebral cortical vessels by these intravascular clots.

Dr. SPRATLING (Sonyea, N.Y.), was to have given a Kinetoscopic Exhibition of Epilepsy but was prevented owing to unforeseen contingencies; he gave, however, a brief account of the technique of the process and showed one of the kinetoscope films.

Dr. ALDREN TURNER opened a discussion on

Epilepsy

by reading a paper dealing with psychical epileptic equivalents under the following heads: definition and general clinical features; psychical epilepsy and epileptic ambulatory automatism; masked epilepsy; post-paroxysmal psychoses; and varieties of psychical equivalents seen in epileptic mania, impulsions, and katatonic and transitory delusional states. He referred to psychasthenic conditions and the psycholepsy of P. Janet as a paroxysmal equivalent. Inter-paroxysmal "aura" sensations he did not look upon as true equivalents. Reference was made to narcolepsy.

The PRESIDENT dwelt upon the enormous number of mental states of the most varied kinds or forms which occur as epileptic equivalents and also upon the difficulty of diagnosing in some cases between epileptic equivalents of certain kinds and conditions which were part of many cases of epilepsy and, on the other hand, mental besetments or psychasthenic obsessions. He referred to P. Janet's view that psychasthenia generally constituted a mitigated epilepsy —a view from which he dissented.

Dr. MILLS also dissented from P. Janet's views on this point. He thought that a distinction should be made between psychasthenic obsession and epilepsy.

Dr. SPRATLING referred to the extreme rarity of pure psychical attacks without epilepsy—only ¼ per cent. of all attacks, while cases of psychical attacks interspersed between epileptic fits, *grand* or *petit mal*, occurred in the proportion of 5 per cent. of all attacks. He considered the dreamy state as over-estimated; it represented in most cases an intellectual aura preceding an attack. With reference to the study of epilepsy he thought that neuro-pathology had had its day. At the Craig Colony they were now searching the body of the living epileptic for the cause of the epilepsy. He looked upon the convulsion as the salvation of the epileptic's mind.

Dr. W. S. SPILLER (Philadelphia) referred to Friedmann's and Oppenheim's attempt to separate from epilepsy certain groups of cases usually classed as epilepsy. He described a case under his observation for five or six years which might be regarded as one of psychic epilepsy but which he considered as belonging to the psychasthenic group of cases.

OPHTHALMOLOGY.

TUESDAY, AUGUST 21ST.

There was an excellent attendance of members when Mr. R. MARCUS GUNN, the President, opened the session with a brief address of welcome. Before commencing the business of the day Mr. Gunn alluded to the great loss sustained by the profession, and by ophthalmology in particular, by the death of Dr. Buller of Montreal.

Mr. J. B. LAWFORD (London) introduced a discussion upon

Rare Forms of Choroiditis.

He especially desired to elicit opinions upon the etiology of some forms of choroidal disease, rare in his experience, which he proposed to bring before the meeting. The first group contained cases of widespread changes in the choroid closely resembling the disseminated choroiditis of syphilis but in which no syphilitic taint could be found; the second group was a form of choroiditis to which the term "localised exudative choroiditis" might be applied; whilst the third group was "family choroiditis," in which the disease attacked two or more members of a family and presented considerable variation in type.

Mr. A. Hill Griffith (Manchester) mentioned three rare varieties of choroiditis—one a limited choroiditis occurring in company with a descemititis, a second variety of plastic localised exudation, and a third variety commonly known as macular coloboma.

Dr. Stedman Bull (New York) had seen a number of cases of localised choroiditis occurring in young persons without any evidence of syphilis. The site of lesion was always near the optic disc or macula.

Dr. Risley (Philadelphia) called attention to a group of relatively rare forms of choroiditis which seemed to bear some relation to disease of one of the bony sinuses of the skull.

Mr. Arnold Lawson (London) cited two cases, one of which was an instance of localised choroiditis occurring with a keratitis punctata and limited vitreous change, and the other an instance of bilateral severe choroiditis in a boy the subject of chronic dyspepsia the result of severe pyorrhœa alveolaris. The treatment of the dyspepsia and the teeth effected a very marked improvement in the condition.

Dr. Webster Fox (Philadelphia) mentioned a rare case of choroiditis which seemed to follow an outbreak of cholesterine crystal formation in and about the macular region.

Dr. F. H. Verhoeff (Boston) read a paper on Obstruction of the Central Retinal Vein, illustrated by lantern slides. He gave the results of anatomical examination of six cases and expressed his belief that all the cases could be explained by the occurrence of an endophlebitis proliferans without thrombosis.

Dr. Casey Wood (Chicago) read a paper on Poisoning from Wood Alcohol. The characteristic ocular lesion was an optic neuritis going on to a post-neuritic atrophy and permanent blindness.

Dr. W. M. Killen (Belfast) gave a detailed account of McKeown's Irrigating Apparatus for the Extraction of Immature Cataract.

Dr. A. Freeland Fergus (Glasgow) read a short paper explanatory of his Method of Testing Binocular Vision.

Wednesday, August 22nd.

The Section was well attended, the room being crowded, over one hundred members being present at the time. The morning's work was largely occupied by a discussion upon

Sympathetic Ophthalmitis,

which was introduced by Mr. G. H. Burnham (Toronto). He took as his text the treatment of the eye sympathetically inflamed and the transmission of the disease from one eye to the other. He advocated the use of the combined treatment during the quiescent period after an injury before symptoms of inflammation appeared in the other eye.

Mr. Lawson read a paper dealing especially with

The Preventive Treatment of Sympathetic Ophthalmitis.

He pointed out that what was most needed were more authoritative lines upon which a surgeon could base his decision upon the propriety of attempting to save a dangerously wounded eye and which would guide him through the dangers and difficulties which might follow the attempt. Broadly speaking, there was no difficulty in a large number of cases of perforating wounds because the character of the wound and the extent of the injury had utterly destroyed all chances of saving the eye as a visual organ, and it was only in a few instances of this sort that cosmetic reasons would in the slightest degree justify a surgeon in running any risk of sympathetic ophthalmia by attempting to save the eye. But there remained a large class of cases which presented considerable difficulty and which must cause great anxiety. After enumerating and discussing these cases Mr. Lawson went on to summarise the whole matter by putting it in the form of five questions, each of which was discussed in turn. He urged the formation of a committee to inquire into and to collect evidence on the points he had raised.

Dr. J. W. Stirling (Montreal) confined his attention to the pathological aspect of the disease and pointed out that definite progress had been made in this department during the past year and that a distinct type of traumatic uveitis had been discovered. Further, a bacillus had been found the inoculation of which into the vitreous and circulation of a rabbit had set up a uveitis similar to that seen in sympathetic ophthalmia.

Dr. Theobald (Baltimore) was of opinion that congestion and tortuosity of the central retinal vessels, especially those below the disc, foretold commencing inflammation at the posterior pole of the eye, whilst a similar condition of the lower subconjunctival vessels betokened an inflammation of the anterior segment of the globe.

Dr. Weekes (New York) wished to draw attention to a small-celled infiltration of the uveal tract, and particularly of the ciliary body, that he had noted in five cases in which the disease had arisen after a prolonged period of quiescence. He believed that evidence of threatened sympathetic disease was present when such an eye showed evidence of deep-seated inflammation.

Dr. Verhoeff thought that recent infection of the scar accounted for some cases occurring after several years of quiescence.

Dr. Connor (Detroit) advocated treatment of the disease by large doses of salicylate of soda.

Dr. Colin Campbell (Toronto) recorded a case in which typical symptoms of the disease arose when the other eye had suffered from a chronic marginal ulceration of the cornea without perforation.

Dr. Risley had noted that in cases of true sympathetic irritation the symptoms often seemed to have a definite relation with strain upon the ciliary muscle of the injured eye.

Dr. E. L. Jones (Cambridge) wished to draw attention to treatment of the disease by subconjunctival injections of corrosive sublimate (1 in 3000) and salt solution.

Dr. Gordon Byers (Montreal) narrated a case of sympathetic ophthalmitis following Mules's operation. The symptoms of the disease first showed themselves a fortnight after operation and a month after the injury.

Dr. Edward Jackson (Denver) read a paper on Accommodation after Middle Life, in which he pointed out that there was no fixity with regard to the accommodative power of elderly people at any particular age.

Mr. Freeland Fergus read an interesting paper upon a condition to which he had given the name Sympathetic Degeneration. He had noted that in many cases in which one eye was severely damaged the other eye underwent a degenerative process characterised by a concentric permanent contraction of the visual field. Though loss of sight was often severe the condition never went on to complete blindness.

Dr. Herman Knapp (New York) read a paper on the Dependence of Accommodation and Motility on the Refraction of the Eye, in which he described an intimate correlation between the degree of ametropia and the degree of heterophoria. He went on to detail his method of testing patients.

Dr. A Duane (New York) criticised Dr. Knapp's assertions and did not think that there was so close an association between ametropia and heterophoria as Dr. Knapp stated.

THE ANNUAL EXHIBITION.

The accommodation provided for the annual exhibition at Toronto was in a series of rooms on the first floor of the main building of the University of Toronto. There were two large rooms placed at the disposal of the exhibitors and a number of smaller ones. Some of these latter were likely to be overlooked, but the exhibition as a whole was very convenient of access and was well attended after the first day. The number of exhibitors was not very large and there were few striking novelties or marked advances in any scientific directions. American firms were numerously represented, Canadian but sparsely, while several well-known British firms sent over interesting and representative exhibits. Special food preparations were numerous, surgical instruments and hospital furniture were fairly well represented, and various publishing firms had stands with copies of recently published works and medical atlases. The electrical and electro-therapeutical exhibits were among the most interesting, and some practical demonstrations were given of the manner of fixing the apparatus. There was but little display of sanitary apparatus and appliances, and no exhibition of motor-cars as has generally been the case in recent years. Some of the exhibits of firms of druggists presented excellent specimens illustrating the preparation of well-known drugs.

In reviewing the exhibits we may adopt the classification employed in previous years. We propose, therefore, to consider the various sections of the exhibition in the following order: (1) Surgical Instruments and Appliances; (2) Drugs; (3) Foods and Food Products; (4) Sanitary Appliances; (5) Mineral Waters, Beverages, &c.; (6) Publications; and (7) Miscellaneous.

I.—SURGICAL INSTRUMENTS AND APPLIANCES.

The exhibits of surgical instruments and appliances and special instrumental methods of treatment attracted more notice than some of the other exhibits. An interesting and extensive exhibit of surgical instruments was that of E. B. Meyrowitz of New York. These were chiefly instruments employed in the diseases of the eye, the ear, the nose, and the throat. Various apparatus for ophthalmological work were shown, including test cases and ophthalmoscopes. The Meyrowitz Javal ophthalmometer was one of the chief items in this firm's exhibit, and in addition there were instruments for testing muscular insufficiencies and for orthoptic treatment, including the Worth-Black amblyscope, the Derby stereoscope, and the phorometer, tropometer, and clinoscope of Stevens of New York. The transilluminator of Sachs of Vienna was also shown, enabling the interior of the eye to be transilluminated through the sclerotic, leaving the pupil free for observation. A complete outfit for ophthalmic operation was also on view. Various forms of otophone were exhibited; this is an instrumental aid to hearing for the deaf, the apparatus ending in a rubber diaphragm which rests against the ear and is not inserted into the meatus. Apparatus for mastoid and other aural operations were also shown. Some special instruments for operations on the nasal septum were prominently displayed, including those of Freer, Killian, and Ballenger. Messrs. Allen and Hanburys, Limited, of 48, Wigmore-street, Cavendish-square, London, W., and of Niagara Falls, New York, and Toronto, Canada, showed some surgical appliances, including operation theatre furniture and various instruments. Their special operation table of phosphor bronze with patent mechanism for altering the position of the patient, which we described in detail last year, was also prominent among their exhibits. In one of the small rooms of the exhibition was the complete assortment of surgical appliances and aseptic hospital furniture for operation theatres shown by Messrs. Down Brothers of 21, St. Thomas's-street, London, S.E. Patent aseptic tables were shown made of rounded steel tube and supporting glass shelves so arranged as to leave no interstices or corners to collect dust or fluid. Messrs. Down Brothers' surgical hand motor with drills, osteotomes and saws for cranial surgery, various instruments for the operation of bone-screwing, and antrum instruments and various forms of midwifery forceps and of other apparatus for special surgical operations were also in this exhibit. A small glass instrument cabinet for eye instruments was noteworthy, the sides being of opaque glass to prevent the instruments from being seen by patients. The Globe Manufactory Company of Battle Creek, Michigan, exhibited some ingenious and useful forms of apparatus for the fine division of various solutions. The "Globe" multinebuliser enables solutions of different kinds to be nebulised by means of one mechanically controlled pump and could be adapted for inflation of the middle ear and for the application of medicated vapours to the mucous membranes of the air passages. There were also various forms of pump, including an automatically controlled electric air pump and a hand-power pump. Some of the instruments were adapted for vibratory stimulation and massage and the degree of force employed was capable of regulation. This exhibit was an interesting one and practical demonstrations of the mode of working the nebulisers and vibrators were given. The De Vilbiss Manufacturing Company of 1218–1220, Jackson-street, Toledo, Ohio, U.S.A., and Windsor, Canada, showed various forms of atomisers, nebulisers, and powder blowers. The Clark and Roberts Company, of 315, Holton-place, Indianapolis, Indiana, showed some specimens of furniture for wards and consulting rooms, including the specialist's cabinet and chair, made of metal and capable of various adjustments. The Bausch and Lomb Optical Company of Rochester, New York, furnished some microscopes of good pattern and well-finished characters with firm stands and good adjustments. An improved Minot rotatory microtome with several new features possessed good adjustments for varying the position of the object to be cut and for regulating the thinness of the section desired. The J. F. Hartz Company, Limited, of Toronto, Ontario, and Detroit, Michigan, acted as agents in charge of several exhibits, among them the Victor Electric Company's electrical apparatus; for the Spencer Lens Company, Buffalo, New York, who showed some microscopes with a new form of fine adjustment and with automatic lubrication of both coarse and fine adjustments; for the Scanlan Morris Company of Madison, Wisconsin, who exhibited operating and instrument tables with porcelain tops; and for the Leucodescent therapeutic lamp. This was an exhibit of considerable interest. The apparatus consists of a single globe containing the incandescent form of electric lamp with a candle power of 300, 400, or 500. The globe is placed in a conical protecting hood. It is stated that the rays from this lamp form a faithful representation of sunlight and that the heat rays, the luminous rays, and the blue violet rays are all utilised in the apparatus. An interesting exhibit was the high-frequency and x-ray apparatus of the Electro-radiation Company of Boston, Massachusetts. Various forms of coil were shown, such as the "Hercules" and the "Ajax," with x-ray tubes and other apparatus. The Electro-Surgical Instrument Company of Rochester, New York, exhibited various forms of electrically lighted surgical instruments, including cystoscopes, urethroscopes, specula of various kinds, and gastro-diaphanes. The Dowsing Radiant Heat Company of London showed various forms of appliances, including an ingenious instrument, the "Arthromotor," which is an apparatus devised to apply active and passive movements to any joint of the extremities. It is capable of numerous adjustments and the amount and speed of the movement can be readily graduated and varied at will. The Stabbe Therapeutic Lamp Company of 709–710, Omaha Buildings, Chicago, Illinois; Messrs. T. A. Houghton and Co. of 123, Mill-street, Rochester, New York; and Messrs. C. F. Birtman of Chicago, Illinois, exhibited various electrical and electro-therapeutical apparatus.

II.—DRUGS.

At the annual exhibition owing to the never-ceasing labours of the pharmaceutical chemist and the continued succession of synthetic products yielded by the laboratory we may generally expect to find a number of new preparations or of new drugs. This year, however, the number was comparatively few, and more attention is now being given by the manufacturing druggists to the preparation of animal products and of curative sera. Although the number of exhibits dealing with drugs and pharmaceutical products was not large some of the preparations were of considerable interest. The stand occupied by Messrs. Parke, Davis, and Co. of Detroit and of 111, Queen Victoria-street, London, E.C., was of considerable interest as illustrating the application of recent bacteriological research to diagnosis and treatment. There were some flasks of experimental anti-sera which are being tested and are not yet upon the market, including anti-scarlet, anti-typhoid, anti-pneumococcic, anti-dysenteric, anti-gonorrhœal, and anti-streptococcic sera. A number of large tubes, 32 inches by 2 inches, contained cultures of various pathogenic and chromogenic bacteria. The typhoid agglutometer for applying the Widal test for typhoid fever, to which reference has already been made in our columns, was also exhibited. The methods used in the preparation and standardisation of drugs were also illustrated. A new preparation was thyroidectin, the dried blood serum of sheep and goats from which the thyroid gland had been removed, which is now used in the treatment of exophthalmic goitre. Messrs. H. T. Kirby and Co., Limited, of 14, Newman-street, London, W., showed specimens of purgen and of soft glycerine lozenges called glycecols, which seemed to be convenient and useful for the administration of some drugs. Phytin, a non-poisonous phosphorous preparation obtained from plant seeds, containing 22·8 per cent. of organically combined phosphorus, was exhibited by Messrs. Louis Ritz and Co., Hamburg, Germany. Fortossan, a soluble compound of phytin and milk sugar, suitable for infants and children, was shown by the same firm; also Salen, a new salicylic ester for the local treatment of rheumatism. Messrs. C. J. Hewlett and Son of 35–42, Charlotte-street, London, E.C., showed numerous pharmaceutical preparations and proprietary preparations, including the Mist. Pepsinæ co. cum Bismutho. A soluble preparation of iodine, non-irritating, and capable of hypodermic injection, was exhibited by the Burnham Soluble Iodine Company of Auburndale, Massachusetts. A stall was devoted to Antiphlogistine, prepared by the Denver Chemical Manufacturing Company of New York. Some pharmaceutical products of interest were on view in the exhibit of Messrs. Rigaud and Chapoteaut of 8, rue Vivienne, Paris; among them we may mention Apioline, the active principle of parsley, recommended in certain menstrual disturbances; Cerevisine, consisting of pure desiccated yeast cells; and phosphoglycerate of lime. The well-known products of Messrs. Fairchild Bros. and Foster of New York were exhibited, including panopeptone. Among their exhibits were hypodermic injections of trypsin and amylopsin and holadin—an extract of pancreas rich in trypsin, amylopsin, and lipase. Dioxygen, formerly known as Oakland hydrogen peroxide, which was stated to be available for internal use, was shown by the Oakland Chemical Company of 464, West Broadway, New York. Messrs. Allen and Hanburys exhibited their various well-known Bynin preparations, infant foods, and cod-liver oil. Kapsoli were also to be seen; these are a new form of pill inclosed in a thin, soft, and readily soluble *jujube coating*. Messrs. Burroughs Welcome and Co. of London, Sydney, and Cape Town, presented an exhibit of their well-known tabloid preparations, of the "Wellcome" brand of chloroform, of antitoxin for diphtheria, and of "enule" suppositories. In the exhibit of Messrs. Duncan, Flockhart, and Co., of Edinburgh, the various anæsthetic preparations for which this firm have been so long known were shown, also various forms of special pills and other pharmaceutical products. The useful preparation of Glycothymoline was shown by the Kress and Owen Company of 210, Fulton-street, New York. Messrs. Henry K. Wampole and Co. of Perth, Ontario, exhibited preparations of cod-liver oil, phospholecithin, various terpin compounds, and other special preparations. Various preparations of lactopeptine were on view at the stall of the New York Pharmacal Association, Yonkers, New York, among them the tablets, the elixir, and the elixir with phosphate of iron, quinine, and strychnine. The Palisade Manufacturing Company, of Yonkers, New York, exhibited its preparation Hæmaboloids which are stated to consist of *natural iron containing nucleo-proteids, extracted from* vegetable structures, reinforced by a synthetic organic iron compound, nutrient albuminoids, the hæmatinic principle of bone marrow, and some nuclein. Tubes illustrating the preparation of these substances were on exhibition. The Charles Phillips Chemical Co. of 128, Pearl-street, New York, exhibited a number of special preparations; among them we may mention the phosphomuriate of quinine and the milk of magnesia, to which we have drawn attention on previous occasions. Nepenthe, the preparation of opium prepared by Messrs. Ferris and Co., of Bristol, England, was shown among their exhibits, also various dressings and "caddies." The "ever-ready" caddy consists of a dust-proof receptable for dressings, so arranged that the required quantity can be readily unrolled and cut off. Messrs. Reed and Carnrick of Jersey City, New Jersey, had on view samples of protonuclein, peptenzyme, pancrobilin, and nephritin, the latter being an extract of the cortex of the kidney. The Abbott Alkaloidal Company, of Chicago, New York, Seattle, and London, exhibited granules and tablets containing a definite quantity of pure alkaloid, glucoside, or other active principle.

(*To be continued.*)

Salisbury Infirmary.—The annual meeting of the governors of the Salisbury Infirmary was held on August 31st under the presidency of the Earl of Radnor. The medical report stated that during 1905 the in-patients numbered 855 (an increase compared with 1904), the average stay of each in the institution being 20 days. 2936 out-patients and casualties were treated The financial statement showed that although at the end of 1904 there was a debt on the general account of £3747 and on the building account of £1152, at present there only remained a debt of £1080 on the general account, the building account had been paid, and it was added that for the first time for many years the income had met the expenditure. The Earl of Radnor alluded to the manner in which the medical staff assisted at the recent railway accident, and a special vote of thanks was awarded to them for their excellent services on that occasion.

THE OUTBREAKS OF PLAGUE IN TURKEY.

(From the British Delegate to the Constantinople Board of Health.)

Since the date of my last letter, which appeared in The Lancet of August 25th, p. 525, there have been no further cases of plague in Jeddah. The outbreak there seems to have come to an end in the last week of July and fortunately, with the exception of the two imported cases mentioned in my previous letter, there has been no extension of the disease to Mecca. All preventive measures except a simple medical visit have now been removed from arrivals from Jeddah.

Two more cases of plague, making ten in all, have been reported from the prison at Trebizond. The ninth occurred on August 18th and then, after an interval of 11 days without any fresh cases, a tenth was reported on the 29th. It appears that, in spite of urgent recommendations to *evacuate the whole prison if possible, and if that were* impossible to remove at least the prisoners from the infected ward, no measure of the kind was taken until August 20th, when 196 prisoners were transferred to the mosque of St. Sophia; but it was not until the 25th, or 19 days after the appearance of the disease, that the prisoners occupying the infected ward were transferred to another. Later reports state that the total number of prisoners in the prison was between 400 and 500 and not over 700, as at first stated, but the authorities themselves admit that the prison was crowded and insanitary. Preliminary reports have been received from the two bacteriologists sent to Trebizond from Constantinople; bacilli resembling morphologically the plague bacillus were observed microscopically in one of the earlier cases and those isolated from the last case not only gave characteristic cultures on gelatin but also, when inoculated into guinea-pigs, produced characteristic lesions in the organs from which the same bacillus was obtained.

At Adalia, on the southern coast of Asia Minor, two suspected cases of plague have been recently observed. The first case to which attention was called was seen on the evening of August 24th. The patient was a grocer ("épicier"), aged 29 years, living in the Tashlik quarter of the town. He was said to have fallen ill on the morning of the 23rd The symptoms, as briefly described in the telegrams, were those of an acute attack of bubonic plague, with the bubo in the left groin. He died at 9 P.M. on the 24th. On inquiry it was then found that a female servant in the same house, aged 20 years, had been taken ill seven days previously with high fever and other suspicious symptoms. When examined this patient was found to be convalescent but there was still a suppurating bubo in the groin.

In consequence of these cases a quarantine of 48 hours, with disinfection and application of the circular concerning rat destruction, was imposed against Adalia; and, no fresh cases having occurred in the interval, these measures were reduced on the 4th inst. to simple medical visit, with disinfection and application of the rat destruction circular. Nothing is known as to the origin of the infection in these cases. It will be recalled that a small outbreak of plague occurred in Adalia in the months of July and August of last year, and then, as now, their origin could not be traced. It is stated that the infected house is situated far from the sea and that the man who died was a poor grocer having no direct relations with importers from Egypt or elsewhere. It is added, however, that in a ditch behind the infected house some ten dead rats were discovered. It is also stated that the female patient had recently put on a dress that had belonged to a woman who suffered from plague in last year's outbreak, to whom she was related, and that this dress had been carefully hidden to avoid its being burnt with the other contaminated effects. The fact, if it be a fact, is of interest, though it would seem more logical to suppose that if the present cases were due to a revival of last year's infection the infective material has been kept alive by a succession of rats than to assume that it has lain dormant for a year in the folds of a dress. A bacteriologist has been sent to Adalia from Beirut to investigate the nature of the disease.

LONDON: SATURDAY, SEPTEMBER 15, 1906.

"Return" Cases of Scarlet Fever.

RATHER less than a year ago we commented on a report issued by the Metropolitan Asylums Board on the subject of "return" cases of scarlet fever and diphtheria—cases, that is to say, which arise owing to infection conveyed by patients discharged as cured from the hospitals over which the Board presides.[1] That report was drawn up by Dr. A. G. R. CAMERON on the basis of returns extending over a period of 13 months, and embodied certain suggestions calculated to diminish risk from this source of infection. The period of time covered by the report was, however, obviously insufficient to allow any very certain conclusions to be reached, and we expressed the hope that further investigations would be made into a matter which so deeply concerns the welfare of the community. We are glad to see that this view has commended itself to the authorities of the Metropolitan Asylums Board and that the results of further study of the problem are now available. The present report is written by Dr. F. M. TURNER, the medical investigator for the Board, and is distinguished by the same industry and ability which characterised Dr. CAMERON'S work. Unfortunately, although the figures for three years are analysed, thus affording a more trustworthy statistical basis, the practical conclusions reached are no more encouraging than those of the former observer. Indeed, the result of the present investigation is to contradict or neutralise some of the conclusions which the earlier series of figures appeared to warrant.

Among the principal points emphasised in Dr. CAMERON'S report were the following two—that a large proportion of so-called "return" cases were in reality the result of mere coincidence—instances of purely accidental outbreaks of scarlet fever in houses to which cured patients had recently returned from hospital; and that in the majority of cases in which infection had really been conveyed by the discharged patient rhinorrhœa had been a feature of his attack, such nasal discharge being, therefore, the probable means by which infection was carried. The fact that "return" cases were most frequently met with in autumn and winter seemed to favour this mode of infection, as suggesting that a chill with consequent increase of coryza might have been contracted as a result of exposure to the cold outer air. Dr. TURNER has carefully tabulated statistics of 1000 consecutive cases at the Eastern Hospital, at which a careful record was kept of all cases showing rhinorrhœa, and he finds that while among 397 cases without complications of any kind 3·27 per cent. caused infection on returning to their homes, among 343 cases with rhinorrhœa only 2·62 per cent. proved infectious. Among 256 cases with other complications only 1·54 per cent. caused further outbreaks. The figures certainly appear to negative the suggestion that sufferers from nasal discharges are those most likely to convey infection. On further scrutiny of the figures there is, however, one point at least which deserves consideration in order that we may be sure that we are not drawing erroneous inferences. Thus it appears from the tabular statement showing the dates of discharge of the 1000 cases used for this inquiry that, whereas the "return" infectivity rates for cases without complications or with other complications than rhinorrhœa discharged after less than eight weeks' detention were respectively 3·6 and 3 per cent., cases with nasal discharge similarly treated showed a percentage of over 6·6 "return" cases. The low proportion of infective cases among the whole number of cases of rhinorrhœa may be due to the fact that no less than 180 patients who had exhibited this complication were detained in hospital over ten weeks, by which time the nasal infection had very probably become attenuated. In view of these considerations it would seem at all events premature to discard Dr. CAMERON'S warning as to the special danger attaching to these cases, at all events when they are discharged from hospital after only a short period of detention. It is to be regretted that at present the causal organism of scarlet fever is unknown, so that bacteriological examination cannot afford any assistance in determining the presence or absence of infection. It is remarkable, however, that in the case of diphtheria, in which the bacillus is easily found, insistence on a free bill of health from the bacteriologist has not tended to lessen the number of "return" cases arising at the institutions enforcing this method of precaution. Another feature of this recent report which is the reverse of reassuring is the practical contradiction of Dr. CAMERON'S contention that a large number of "return" cases of scarlet fever are pure coincidences. It thus appears that the public danger from discharged cases of this disease is very real. On the other hand, it must be borne in mind that at the present day scarlet fever is a comparatively mild ailment—it has even been suggested by Dr. L. C. PARKES that it might safely be treated as measles is, the patients not being removed to isolation hospitals. Dr. TURNER'S figures do not tend to support the belief that the mortality of "return" cases is greater than that of other patients, a suggestion that was in any case contrary to probability on theoretical grounds.

A somewhat curious point in which the present report is in agreement with the former is that a larger proportion of infecting cases is found among those patients who are detained for periods varying between eight and 12 weeks than among those whose stay in hospital is either shorter than eight or longer than ten weeks. It is legitimate to suggest that the reason for this peculiarity is to be seen in the fact that cases discharged in less than eight weeks are instances of mild infection, in which the power of contagion is also mild, while, on the other hand, a detention of over ten weeks usually gives time for the infective agent to die out. Another point in which the two reports are in accord is in uprooting the ancient belief in the special contagiousness of the peeling stage of the disease. We read in the present report: "The above figures are, therefore, what we should expect if late desquamation has no relation to power of conveying infection. If any such connexion exists it must be insignificant in amount." It is, however, unfortunate that while taking away this old criterion of infectivity our more recent mentors supply no other test to take its place. The difficulties of investigating in this direction are, however, very considerable in view of the multiplicity of fever hospitals and of the necessarily promiscuous manner in which cases from any one district are sent to one or another of them according to the existence of vacant beds. "Return" cases from one hospital are thus often sent to another, and the difficulty of tracing sources of infection is greatly increased. We congratulate the able medical officers of the Asylums Board on the extent to which they have overcome the difficulties presented, and hope that the subject of "return" infection may continue to receive attention at their hands in years to come. The matter is one upon which the public requires precise medical guidance.

◆

A Medical View on Facilities of Transit.

THE attention of the summer meeting of the British Association for the Advancement of Science was not strictly confined to the class of questions which would at first sight appear to be suggested by its title; it was extended to some which fall rather within the domain of sociology, and many of these had sides of medical interest. Considerations relating to density of population upon urban areas, and to the means by which the ordinary effects of such density may be diminished or controlled, are matters that are now being daily discussed by sanitarians of all sorts. At the meeting of the Association a paper was read by Professor E. MAHAIM upon Cheap Railway Tickets for Workmen in Belgium, another by Dr. LYNDEN MACASSEY on the Distribution of Population by Facilities for Rapid Transit, and a third by Mrs. (or Miss) MARY E. WOOD on Industrial Betterment, all dealing with one or another aspect of locomotion as a remedy for overcrowding and for the many sanitary and social evils which it involves, and the information given and views expressed might be considered with advantage by many of our own municipal authorities, within whose several boundaries these evils are more or less conspicuously apparent. It is necessary to speak with all reserve when comparing conditions practically known to us with others which are known only by description; but, subject to this reservation, it certainly appears from the account given by Professor MAHAIM that Belgium has at least approached an entirely satisfactory solution of one of the greatest social problems of the day. The railway companies in Belgium have seen their way to the institution of cheap trains for workmen to and from all parts of the territory, and for these trains weekly tickets are issued at very low fares. The weekly ticket for six daily return journeys costs less than one ordinary third-class return ticket, and the average length of each journey in 1904 was about 11 miles. The average fare was 12 centimes or less than five farthings of our money. The system was established in 1869 and at first progressed but slowly. In 1888 the number of weekly tickets sold was 11,000,000. It reached 21,000,000 in 1895, and 53,000,000 in 1905, when it was estimated that the tickets were used by one-sixth of the total industrial population. The practical effect is said to be that the country is rapidly becoming a single market, in which distances have no effect upon the price of labour. Moderate rents and other advantages, such as gardens with vegetables, have retained many town workers as dwellers in country districts, and town rents have been kept down by country competition. It is urged that the workers who travel to and fro every day avoid the promiscuous intermingling of the sexes which is so frequent a consequence of urban overcrowding, that the cheap trains tend powerfully to educate the travellers, and to promote the mobility of labour and the possibility of finding work in times of local slackness, as well as to equalise competition. Obviously they also afford to the sick the means of seeking an improved environment.

If we contrast this description with the state of things existing around us in London—and the problems in London may be regarded as the exaggeration of problems existing in other centres—the comparison cannot be said to be to our advantage. It is necessary, of course, to remember that the numbers to be dealt with in London are vastly larger than in Belgium, and that our suburban railways, besides being already taxed to the full extent of their powers, have been constructed at a cost relatively so enormous as to be prohibitory of very low fares. We have, therefore, to deal with different primary conditions. Not the least important of these would be the distance to be travelled in order to reach localities in which the price of land and other conditions would be such as to promote the construction of workmen's dwellings. The London County Council from the time of its first institution has been eager to afford facilities for industrial locomotion, and it may be doubted whether its more ardent spirits have always retained sufficient respect for the rights and the property of railway shareholders, who, there can be no question, have more than once had reason to congratulate themselves upon the protection afforded to them by Imperial Parliament. But, within wide limits, Parliament has allowed the Council to have its own way, and, judging by the present position, the wisdom which has presided over its decisions is not always apparent. The Council has set up a tramway system, the working of which may at present be studied in the southern and south-western suburbs, which are served by frequent cars running from the principal bridges and propelled by electricity on the "conduit" system. The lines for these tramways have been laid along the old coach roads, by the sides of which, for miles out of London, there still exists, an unbroken succession of dwelling houses of good construction, ranging in kind from stately mansions with large grounds to modest villas, worth in the days of their prosperity perhaps £150 a year. As an incident of tramway construction the whole of this roadside property has been depreciated to an extent the total of which could only be stated in millions, and it is depreciated as far as can be seen for every conceivable purpose. On many of the suburban roads two out of three of the comfortable houses which fringe them are to let, and there is no probability of their ever finding tenants. The medical profession is taking its share in putting down the value of this property by warning intending tenants solemnly against it. The noise of the tramway service is deafening and it is incessant. The creak and rattle and roar of the cars are only varied by the loud and discordant jangling of their gongs. The cars run from daybreak until midnight without intermission; indeed to certain points they run all night through at half-hour intervals. Facilities of transit, when they mean a fluid population and a rapid interchange of labour, are enormous blessings—their medical significance can be seen at once; but if the result of scientific endeavour towards such ends is the creation for a long period of an uninhabitable belt, the future uses of which it is impossible to foresee, medical men and sanitarians will all conclude that our recent endeavours have not been on the right track. For neglected, depreciated, and uninhabited house-property soon becomes a veritable nidus of disease and crime.

The Mortality of Children from Overlying or Accidental Burning.

A CONFERENCE was held late in the summer, it may be remembered, under the presidency of the Earl of ANCASTER, between some members of the executive committee of the National Society for the Prevention of Cruelty to Children and a deputation consisting of members of the Coroners' Society and of the British Medical Association. The subject of the conference was the frequency of deaths among infants from overlying or from accident arising out of neglect on their parents' part to guard them against the perils of fire. We referred in THE LANCET recently to the question of the prevention of overlying (a term which we venture to prefer to the obviously incorrect "overlaying" usually employed), and we have upon many occasions urged upon the consideration of legislators that the deaths of children occurring through their being left alone in rooms with unguarded fires is a matter with which the law might well interfere. There is no need for us to insist upon the importance of these topics in the eyes of all humane persons, and we are more concerned at present in considering possible remedies; but it may be useful to mention that, looking back upon the last six years, in 1903 there were 1619 deaths among children going to bed with their parents and 1660 in 1904, and that the returns made by 200 coroners show that within their jurisdictions 1634 children were burned to death in the years 1899 and 1900, 1425 of these cases occurring where there was no fire-guard. What are the remedies that have been proposed? Suggested legislation we find generally takes the form of additions to the existing law relating to cruelty to children, making it criminal exposure or neglect of a child to leave it in a room with an unguarded fire or to take it into the bed of its parents. We also find that, when the Act dealing with cruelty to children which is now in force was passed in 1904, Mr. BENJAMIN WAUGH, of the National Society for the Prevention of Cruelty to Children, tried to get included in it two clauses or subsections as follows: "The offence of 'exposure' shall further include the leaving of a child alone in a room with an unprotected fire," and "The offence of 'exposure' shall further include the perilous overcrowding of any infant in bed or the going to bed drunk with any infant." These clauses were, however, struck out, presumably in the face of opposition in Parliament, emanating from persons afraid lest the poor should be exposed, by their insertion, to penalties for offences due only to their poverty. Opposition on such grounds was reasonable, but the difficulty might have been got over.

At the conference of which we are writing Mr. C. L. ROTHERA, the coroner for Nottingham, suggested similar legislation to this but upon slightly different lines, making, so to speak, the starting point of criminal proceedings the death of a child upon whose body an inquest has been held, and whose death should be found to be due to either of the two causes referred to. The sections which he proposes should be added to the existing law run as follows:—

> 1. Whenever upon an inquest taken upon the body of a child under three years of age it is found by the jury that death has been caused by suffocation while the child was in bed with its parents or other adults, and that the suffocation was not the result of natural causes or of the presence of any foreign body in the throat or air passages, such finding shall be evidence that such parents or other adults have neglected such child in a manner likely to cause unnecessary injury to its health within the provisions of Section I. of the Cruelty to Children Prevention Act, 1904.
>
> 2. Whenever upon an inquest taken upon the body of a child under ten years of age it is found by the jury that death has been caused through (*a*) burns sustained by the clothing of the deceased child taking fire at an open fire-grate, or (*b*) by scalds caused by the child having access to any vessel of hot liquid on the bars or hobs of an open fire-grate, the absence of an efficient fire-guard around such fire-grate shall be evidence of neglect on the part of the parents or other persons having the custody for the time being of such child under Section I. of the Prevention of Cruelty to Children Act, 1904.

The conference appeared generally to be in favour of legislation, but no definite opinion was expressed upon the relative merits of the two possible courses above indicated, and those present were fully sensitive of the difficulties attending legislative interference with the domestic privacy of the poor. We would point out that the proposition, which limits such interference to those cases in which an inquest is held, may result occasionally in the punishment of dangerous neglect of small children, but that its effect to *prevent* such neglect will be indirect only, uncertain, and slow. There would also be no punishment in the case of injury by burning, or of any injury by overlying, not resulting in death.

A proposal, however, to make the neglect punishable whenever detected implies inquisitorial methods which will be distasteful to some, and it will also be met by the objection that such an enactment would press hardly upon the very poor who cannot afford separate beds for their infants or to provide even the most rudimentary kind of fire-guard. We are not so sure that these arguments should carry weight. The ingenuity and industry of sober, kind-hearted, and hard-working parents, however poor, will generally be found equal to the task of devising some kind of crib or box for the baby with enough covering to maintain its warmth, though at the expense of a little self-denial to themselves; and we have little doubt that manufacturers could soon meet the demand, which does not now exist, for a fire-guard suitable for the poor. With the parents who are not sober, not kind-hearted, and not hard-working we need have no excessive sympathy if their failure to make any attempt to protect their children from obvious risks attracts the notice of the law. Further, we do not believe that those who would be called on to enforce any new provision of the law would allow it to press heavily upon the good citizen. We are only afraid that they would enforce it too lightly against the undeserving. In Germany, at any rate in some parts of Germany, there is a law that no child shall sleep with its mother. In many cases in which an answer of *non possumus* is given as a reply to a demand for sanitary and other reforms consideration of the example of other countries forms a valuable guide in estimating the possibility of the improvement at home. We are a little too ready to forget that we are not the only nation in the world which has to amend its laws in order to keep pace with the developments of modern civilisation.

Annotations.

"Ne quid nimis."

TRANSMISSION BY POST OF PATHOLOGICAL SPECIMENS.

THE Postmaster-General has recently revised the regulations governing the transmission by post of deleterious liquids and substances sent for medical examination or analysis, and on and from Oct. 1st such specimens may be sent by letter post, without registration, by qualified medical practitioners and qualified veterinary surgeons under the following conditions:—

1. That they are addressed to a laboratory or institute, public or private, or to a medical practitioner or veterinary surgeon within the United Kingdom.
2. That they are inclosed in a receptacle hermetically sealed, which receptacle must itself be placed in a strong wooden, leather, or metal case in such a way that it cannot shift about and with a sufficient quantity of some absorbent material (such as sawdust or cotton-wool), so packed about the receptacle as absolutely to prevent any possible leakage from the package in the event of damage to the receptacle.
3. That they are conspicuously marked "Fragile, with care," and bear the words, "Pathological specimen," and also the signature and address of the medical practitioner or veterinary surgeon who sends them.

The packet must on no account be sent by parcel post. Any packet of the kind found in the parcel post, or found in the letter post not packed and marked as directed, will be at once stopped and destroyed with all its wrappings and enclosures. Any person who sends by post a deleterious liquid or substance for medical examination or analysis otherwise than as provided by these regulations is liable to prosecution. It is recommended that if receptacles are supplied by a laboratory or institute to medical practitioners or veterinary surgeons they should be submitted to the General Post Office, in order to ascertain whether they are regarded as complying with the regulations.

VIVISECTION IN GREAT BRITAIN AND IRELAND.

THE return recently made by the inspector (Professor G. D. Thane) to the Home Secretary upon experiments on living animals is of a nature to carry comfort to the minds of all reasonable folk, whether their leanings are more pronouncedly scientific or humanistic. On the one hand there is evidence of good experimental work in progress, and on the other there is convincing proof of careful prevention of cruelty. To the antivivisectionist, of course, such a return is sorry reading. That experiments upon living animals should be permitted at all is to him so monstrous that he can only regard the merciful circumstances of modern research with impatience. We may leave him on one side, however, while we recognise gladly the increased use of careful and humane experiment, which goes hand in hand with the more widely recognised need for such work on the part of those responsible for the public health of the country. Several county councils and municipal corporations have their own laboratories in which bacteriological investigations are carried on, including the necessary tests on living animals; many of them have arrangements by which similar observations are made on their behalf in the laboratories of universities, colleges, and like institutions. The Board of Agriculture, too, has laboratories which are registered for the performance of experiments having for their object the detection and study of disease in animals. A large number of the experiments alluded to in the report were made on behalf of official bodies with a view to the preservation of the public health. To any unprejudiced reader of the tables which are included in the inspector's report it is quite plain that licences and certificates are granted only on the recommendation of persons of high scientific standing and that the licensees are fitted by their training and education to undertake the various investigations. Of the experiments performed without anæsthetics the vast majority are mere inoculations or the abstraction of a minute quantity of blood for examination. They were, in fact, such procedures as are in common use upon the persons of human patients, in whose case, however, they are not distinguished by the title of "vivisection experiments."

THE STATISTICS OF THE UNEMPLOYED: AN INTERESTING POINT.

THE problem of the real cause and actual extent of unemployment, now so prominently under discussion, is mainly a social, economical, and political question, but its public health aspect cannot be ignored. A correspondent has recently contributed to the *Times* an interesting article on this subject in which it was asserted that whereas, in consequence mainly of the steadily maintained decline in the birth-rate, the proportion of adults in the English population had increased considerably during the twenty years 1881–1901, the proportion of workers for their support had decreased during that period. This conclusion was based upon statistics derived from the reports on the censuses in the above-mentioned years. As a matter of fact, the householder's schedule used at those censuses required no statement as to whether an individual was in or out of employment at the time of the census, and the reports therefore can throw no direct light upon the question of unemployment. They do, however, show the number and ages of persons stated in the schedules to be following any definite profession, trade, or occupation; they also show the numbers of children and adults not stated to be following any definite occupation, or stated to be living on their own means, or returned as pensioned, or retired from definite occupation. Thus the enumerated population is shown in the tables as either occupied or unoccupied—that is, as following or not following some definite occupation, whether in or out of work at the time of the census. The article referred to points out that between 1881 and 1901 the number of persons returned in the census schedules as not following any definite occupation showed a larger increase than did the number of those persons who were returned as following definite occupation, and it was argued therefrom that the productive force of the nation is declining. As the census figures upon which this conclusion is based relate to the entire population of men, women, and children aged upwards of ten years, in order to estimate the true import of this increase in the proportion of the unoccupied it is necessary to examine the facts for males and females separately. The result of such examination is to show that the increase of unoccupied males aged upwards of ten years between 1881 and 1901 did not exceed 27 per cent., whereas the increase of males at those ages returned as following definite occupations was equal to 31 per cent. Among females at those ages, on the other hand, the number returned as unoccupied showed an increase of 37 per cent., while the increase among those returned as following some definite occupation did not exceed 23 per cent. The number and proportion of males engaged in definite occupations thus showed an increase during the 20 years referred to, whereas the number and proportion of females so engaged had declined. The decline in the proportion of females following definite occupations was one of the most surprising features of the report on the last census in 1901. The marked increase between 1881 and 1901 in the proportion of women engaged in professional and commercial occupations was far more than counterbalanced by the marked decline in the larger number of women engaged in domestic indoor service, in agricultural occupations, and in textile manufacture This is not the place to discuss the economic result of this apparent decline in the definite employment of women of the working-classes apart from their household and family duties, but should this decline be mainly due, as seems to be very probable, to the improved condition of the weekly-wage class, rendering it decreasingly necessary for women to follow definite occupations after marriage, the changes noted may be viewed with satisfaction. Any decline in the proportional employment of married women in definite occupation or handicraft should clearly promote the cause of public health and tend to reduce the present excessive rate of infant mortality. According to the report on the census in 1901 52·3 per cent. of unmarried females in England and Wales, aged upwards of ten years, were engaged in definite occupation, while of the married or widowed women no less than 13·2 per cent. were so engaged; and in Blackburn, for example, 37·9 per cent. of the married or widowed women were definitely employed. No similar information was published in previous census reports, and we must wait for the report on the next census for further explanation of the evidence of the decline in the proportion of women following definite occupations, derived from published census statistics.

THE SOCIETY OF JESUS AND THE HEALING ART.

AN Italian correspondent, writing under date Sept. 8th, says: "The event of the week, ecclesiastical and political, has been the election of the 'Black Pope,' as the General of the Jesuits is familiarly called, and the occasion may be utilised to remind us of what may be set down to the credit of a society not too favourably regarded by the non-Catholic world—namely, its services to the sciences in general and to the healing art in particular. Founded by Loyola to counterpoise, and if possible to defeat, the Reformation promoted by Luther, it pressed into its service every weapon that could reinforce it in the conflict, and, strange as it may seem in an organisation accused of 'obscurantism,' it enrolled the man of science and the medically trained missionary under its banner, inscribed '*Ad Majorem Dei Gloriam.*' In nature-study, as well as in mathematics pure and applied, the Jesuit in the early post-Renaissance period made his mark in nearly every department, and the missionaries of the society, mainly Portuguese, in furtherance of its poet-laureate's ideal—

> 'Loyola Lutheri triumphos
> Orbe Novo reparabit ultor'—

over-ran the new world and the unexplored regions of the old, making converts to the Church and enriching the scientific knowledge already theirs by concurrent observation and research. What visitor to the Vatican has failed to be struck, in the Gallery of the Geographical Maps, with the sagacity of the missionaries who framed them—the watershed of sub-equatorial Africa, for example, being given, hypothetically indeed, but with an approximate accuracy which it was reserved for the latter half of the nineteenth century to complete and to ratify? Again, what student of the medical past has forgotten the beautiful story of the discovery of the quinine-bearing cinchona and the introduction into the physician's armoury of 'Jesuits' Bark,' first exhibited in the seventeenth century, and since then, by pharmaceutical refinements, developed into the salt which is to the European sojourner in the tropics what the Davy lamp is to the miner? Finely told in Sir Thomas Watson's 'Practice of Physic'—a 'professional classic,' if only for the scholarly finish of its language and the artistic cadence of its periods—the story redounds to the credit of the Society but for whose emissary the discovery might have had to wait, who knows how long! Even in the modern day the Jesuit remains true to his scientific traditions—witness those worthy descendants of the Père Boscovich, the Padre Secchi, famed for his 'Solar Physics,' and his successor in the directorate of the Vatican Observatory, the Padre Denza. The latter, indeed, besides his work in seismology perpetuated on identical lines by members of the Society throughout Italy, will always be remembered for his demonstration of the origin of that scourge of the Mediterranean seaboard, the wind known as the 'scirocco.' Having surmised that the said wind was always coincident with a sand-storm in the Sahara, he stationed a correspondent at the border-land between the Tell, as cultivated Algeria is called, and the great desert, with instructions to telegraph to him on the Italian littoral whenever a sand-storm was brewing. '*Detto fatto*'—the correspondent acted accordingly. On came the wind, the Padre Denza being duly prepared for its advent, at various points of the Italian shore, with huge façades of cardboard wet with gum. And sure enough, as it passed oversea inland a thick layer of sand was deposited on the said 'façades,' thus explaining what had been observed, but not traced to its cause, by Celsus—namely, the sense of heat, of weight, of general depression, and lowered vitality experienced during the prevalence of the scirocco—an experience not to be escaped till, by reclamation and crop-culture, the Sahara ceases to be the 'sand ocean' it has been from time immemorial. Inspired by the traditional genius of the Society, the Padre Massaia in his thrilling record of mission work thirty—nay, forty—years ago in the Galla country (west of Abyssinia), ascribes to his nature-study and his command of the healing art the success of the enterprise which brought him the gratitude of the Pope and the title of Cardinal. Setting out as a simple monk about the middle of last century long before the opening up of Egypt to civilisation and the present facilities for travel, he reached the scene of his labours with only the Bible and the crozier of St. Francis. First he began to make friends with the savage natives by teaching them the 'arts of peace' and of civilised life—down to tenement structure, cooking, and clothing. All this time he was quietly mastering their language, till he constructed its grammar for them, and finally translated into it portions of Holy Writ. Then he set up a printing press (thanks to subsidies from the Propaganda) and taught the younger of the natives to read. Still his progress—well-nigh single-handed—was slow, till the periodical outbreaks of small-pox gave him his opportunity. He vaccinated as many of the natives as he could prevail upon to submit to the operation and when the tribe at the next epidemic of the disease found his patients 'immune,' while those who had held back from becoming so either died or emerged from it disfigured, their liking for him deepened into love and a superstitious belief in his power. The success of his mission was then assured. Yes, the poet-laureate of the society was warranted in typifying the mission march of Loyola as that of a well-meaning, beneficent giant:—

> 'Tellus gigantis sentit iter; simul
> Idola nutant; fana ruunt; micat
> Christi triumphantis tropaeum,
> Cruxque novos numerat clientes.
>
> Videre gentes Xaverii jubar
> *Igni corusco nubila dividens,*
> Cœpitque mirans Christianos
> *Per medios saltare Ganges.'*

But it was in the degree in which they reinforced religion with science, above all with the healing art in its widest sense, clinical and hygienic, that the Jesuit apostles effected their most salutary work—a work which made them the progenitors, so to speak, of Livingstone and Bishop Pattison and Dr. Stewart of Lovedale—a work which, if pursued in the spirit of these pioneers, will go far to conciliate for the Society an admiration and a sympathy hitherto withheld from it even among Catholics themselves."

POISONING BY BROMOFORM.

A NUMBER of fatal cases of poisoning by bromoform have been recorded in a recent number of *La Semaine Médicale*. In 1890, shortly after the introduction of the drug into medicine, M. Nonwelaers of Brussels described the case of a child, 15 months old, who died 14 hours after the administration of a mixture which was ordered to be given daily in doses corresponding to 12 drops of bromoform, but this dose was exceeded. In 1902 Dr. Krioull of Wenden reported the case of a girl, aged three years, who died after the daily administration of several dessert-spoonful doses of a 12 per cent. mixture which had been prescribed previously for a child 11 years old. In 1904 Dr. Roth of Brunswick witnessed the death of a child, five years old, from taking a dose of a mixture corresponding to five grammes of bromoform. The child died in coma in spite of medical attention. Quite recently a similar case came to the notice of Dr. Haakma Tresling of Winschoten. A child was told to empty a bottle containing a bromoform mixture which had been prescribed for another member of the family. Instead of obeying he administered it in play to a younger brother, aged four years, with serious results. The child was seized with dizziness, followed by collapse, stertorous breathing, and relaxation of the muscles. It was not found possible to make him vomit, and eventually he succumbed. In this case a dose of from four to five grammes of bromoform proved fatal. As bromoform is so largely used in the treatment of whooping-cough the danger of administering excessive doses should be recognised.

WORKHOUSES AND THE TEMPORARY CARE OF INSANE PERSONS.

A SAD case of suicide recently took place at Chard, the facts of which we take from a full report contained in the *Chard and Ilminster News* of Sept. 1st. Briefly they are as follows. Mr. Napier Close of Chard was visited at his surgery late one afternoon by a young woman in an excited condition who asked him to take care of her. He formed the opinion that she was insane and having sent for the relieving officer, who was not at home, obtained the assistance of a police sergeant, who conveyed her to the workhouse, taking with him the following written message to the master from Mr. Close: "Mary Jane Hayball is suffering from melancholia and has threatened to do away with herself. Please admit her to the workhouse until the return of Mr. Hawker [the relieving officer] who will take over the case." At the workhouse the master refused to accept responsibility and was unwilling to take the patient in, protesting that the workhouse was not a fit and proper place for her, but afterwards he allowed her to be placed in the reception room and Mr. Close himself obtained the services of a woman living in the neighbourhood to take charge of her temporarily. The relieving officer returned to the workhouse about half-past ten at night, took no steps to have the patient removed, and left her in charge of the attendant mentioned. Shortly afterwards she became violent, overcame the resistance of the woman in charge of her, whose cries for assistance were either unheard or disregarded, and escaped through a window, committing suicide by drowning herself before she could be recaptured. The conduct of those in immediate charge of the workhouse and their responsibility in the matter do not appear to have been very closely inquired into by the coroner, who seems to have told the jury that they were not concerned with such questions. The attitude of the Chard guardians, however, seems to be shown fairly clearly by a speech which their chairman made at the inquest before the proceedings began. This gentleman, according to the report referred to, "expressed to the coroner his own regret and the regret of the board on the unfortunate occurrence which had occasioned his (the coroner's) presence that afternoon. He held, and the board of guardians held, that it was not the fault of any of the officers within the walls. They, however, thought that greater care should be exercised by medical officers in admitting cases of that sort to the workhouse. The workhouse was not a lunatic asylum, it was a place for the relief of the poor and others who were from time to time glad to seek refuge there. The workhouse was not a place for people who were *non compos mentis*. He begged to express their deep regret and inform the coroner that they would be very careful to see that in future no persons who were suffering as this poor unfortunate woman suffered would be admitted within the walls." This address seems to be in accord with the views of the board which held a meeting shortly before the inquest took place. We would point out to the Chard board of guardians, however, that while a workhouse is not a lunatic asylum, and possibly the Chard workhouse may be ill fitted for an emergency such as that which occurred, the temporary charge of a person who has suddenly become insane is not by any means an unusual thing to be undertaken at a workhouse, and constitutes a form of relief of the poor which sometimes is greatly and urgently needed. Perusal, moreover, of some of the sections of the Lunacy Acts, 1890 and 1891, should satisfy the Chard board of guardians that the legislature has done its best to provide that temporary safety should be obtainable for the afflicted person in a workhouse until the somewhat complicated machinery provided for his necessary protection can be set in motion. In particular, Section 20 of the Lunacy Act, 1890, orders that "if a constable, relieving officer, or overseer is satisfied that it is necessary for the public safety or the welfare of an alleged lunatic, with regard to whom it is his duty to take any proceedings under this Act, that the alleged lunatic should, before any such proceedings can be taken, be placed under care and control, the constable, relieving officer, or overseer may remove the alleged lunatic to the workhouse of the union in which the alleged lunatic is, and the master of the workhouse shall, unless there is no proper accommodation in the workhouse for the alleged lunatic, receive and relieve and detain the alleged lunatic therein; but no person shall be so detained for more than three days, and before the expiration of that time the constable, relieving officer, or overseer shall take such proceedings with regard to the alleged lunatic as are required by the Act." The question of the control of lunatics, whether paupers or not, with regard to whom it is evidently of urgent importance that they should be placed under care and control, has been considered in framing the Lunacy Acts, with a view to preventing precisely such occurrences as took place at Chard;

nd if it be urged by the Chard guardians that they have no roper accommodation to meet emergencies which at any time ay arise, and which may end in the needless sacrifice of uman life, the answer may be that the introduction of such ccommodation would render their workhouse a more useful nstitution for the relief of the poor of the union. Three ersons seem to have done their best to meet the requirenents of the case above recorded and it is a matter of regret hat success was denied to their efforts: Mr. Napier Close, vho certainly did his utmost in unusually difficult circumtances on behalf of his patient, Police-Sergeant Attwood, nd Mrs. Templeman, who was placed in charge of the nsane person, and who, according to her account, struggled vith her unaided for an hour before she broke away.

THE SUMMER: JUNE, JULY, AND AUGUST.

FOR the purposes of meteorological statistics the three months from June to August are generally taken as comprising the summer in this country, but the heat did not reach its culminating point this year until the 31st of last month or a day or two later. The chief characteristics of the three months here discussed were not their warmth, which was not at all exceptional, but their great and consistent dryness at nearly all places situated towards the south and south-east and in the midlands, and also the large number of hours of sunshine recorded. Of all the places having a sufficiently trustworthy average only two—Scilly and Nottingham—show a deficit, although the excess was only very slight at Aberdeen. Among the localities given in the table the spots with the greatest aggregate number of hours were Jersey, Clacton-on-Sea, Bournemouth, Torquay, Folkestone, Shanklin, and Lowestoft. The greatest excess over the normal, however, was in London (Westminster), where the total sunshine of 693 hours equalled seven and a half hours daily. The large excess of 177 hours for the three months is equal to nearly two hours per day more than the average of the records of the past 25 years warrants. The dullest spots were Glasgow and Manchester, the aggregate hours of sunshine only representing a mean daily duration of a trifle more than five hours at the former city and less than five and a half hours at the latter. The relatively small amount of sunshine at Aberystwyth was due rather to sea fogs and mists than to cloud, and the same unwelcome phenomena also robbed Brighton and a few other resorts on the south coast of several sunny days. The days on which rain fell were about twice as numerous in the north and north-west as in the south and south-east, while in the south-west Torquay especially was noted for its very few rainy days. But everywhere the total fall of rain for the three months was less than the normal. August was, however, rather wetter than usual at many places in the north and north-west. At Clacton-on-Sea rain was only experienced on 20 days and at Lowestoft on 21, against 44 at Blackpool, Harrogate, and Aberdeen, 50 at Glasgow, and 58 at Manchester. A notable example of the effect of local thunderstorms is afforded by the total rainfall at Lowestoft and Great Yarmouth. The Suffolk resort had an aggregate of only 2·44 inches, while at the Norfolk resort, only about nine miles further north, the total yield of the gauge was as much as 5·90 inches. In regard to temperature the summer was remarkable both for the few unseasonably cold spells and for the few extremely hot ones. As a general rule the thermometer was slightly above the average both during the day and night. This is fully supported by the difference from the normal, which, except in a place here and there, showed a slight excess of warmth. The only places with a mean daily maximum of 70° or above were London (72°), Nottingham, Bath, and Bournemouth, and the only spots with a mean minimum as low as 50° were Aberdeen and Harrogate. The warmest nights and most equable temperature were, as usual, experienced in the Scilly Isles, while the places with the greatest diurnal range of temperature were Nottingham, Bath, and London. It is probably only a curious coincidence that the mean temperature at two such dissimilar places as Jersey and Margate was identical. The absolutely highest temperatures registered within the three months all occurred on August 31st. The highest was 93° at Nottingham, followed closely by 91° in London (St. James's Park) and at Margate, 89° at Birmingham and Manchester, and 88° at Bath. During the summer as a whole maxima as high as 80° were very rare and only occurred in the southern, eastern, and inland districts.

* A day with rain is one on which at least 0·01 inch has fallen.

THE TOXIC ACTION AND LOCALISATION OF RADIUM EMANATIONS.

M. Ch. Bouchard and M. V. Balthazard have extended a research, which was first conducted in collaboration with the late Professor Curie, on the toxic action on animals of the emanations from radium, and have determined to what extent the different tissues and organs are affected.[1] They have previously shown that radium emanations are toxic to mice and guinea-pigs when administered by the respiratory tract. By a modification of the method formerly employed they now demonstrate that the emanations are toxic to guinea-pigs when radio-active sulphate of barium is introduced into the peritoneum. Two grammes of the salt, having an activity of 5000 and containing about five to six milligrammes of sulphate of radium, were inserted in a sac of collodion and introduced into the peritoneal cavity under aseptic conditions after laparotomy. Guinea-pigs treated in this manner succumbed on the tenth to the fifteenth day. It was found that the emanations are localised chiefly in the suprarenal capsules, one gramme of which contains as much of the emanations as 4·7 grammes of spleen, 11·4 grammes of lung, 15 grammes of skin, 60 grammes of liver, and 100 grammes of kidney.

---

[1] Comptes Rendus, July 23rd, 1906, p. 193.

FOREIGN BODY IN THE ORBIT FOR NEARLY FOUR YEARS.

IN the *Australasian Medical Gazette* for June Mr. F. A. Pockley has reported the following remarkable case. On May 21st, 1902, a boy, aged nine years, was brought to him for advice. Eight days before, while playing, the boy was knocked against a paling and fell with another boy on top of him. He immediately pulled a splinter of wood out of his right eye and there was slight bleeding. He was stunned by the fall and for two days had headache and occasional retching. When he recovered from the concussion, which was only momentary, he had no perception of light in the right eye and the eyeball was somewhat protruded. On examination the right eye was found proptosed. An inch below the eye and slightly to the nasal side was a small cicatrix. The lower part of the orbit was tender. There was an offensive smell from the eye. The ophthalmoscope showed great swelling and tortuosity of the veins near the disc. Under chloroform an incision was made through the conjunctiva midway between the inferior oblique and the inferior rectus muscles and a splinter of hard wood three-quarters of an inch long and three-sixteenths of an inch thick was removed. Careful probing revealed no other foreign body but the wound was syringed out and left open and a gauze drain was left in for a few days. By May 29th the eye had receded to its normal position and there was no pain or tenderness on pressing it backwards into the orbit. The optic neuritis became much more marked and atrophy of the nerve followed. In February, 1906, the boy was again seen. His mother brought a piece of wood, one and a quarter inches long and one-eighth of an inch thick, which he "had found sticking out of the corner of his eye" on Jan. 31st on waking in the morning. There had been no pain or swelling previously and nothing had been noticed when he went to bed the night before. On the second splinter were dentations which exactly fitted into ones on the first. Cases of foreign bodies being lodged in the orbit for some time without the patient being aware of it are not very rare, but the period is generally much shorter than in the present case, which amounted to nearly four years. In Mr. Brudenell Carter's well-known case a portion of a metal hat-peg, three and a quarter inches long, remained in the orbit two or three weeks without the patient being aware of it. Mr. H. R. Swanzy has recorded a case in which a piece of wood, three quarters of an inch long and half an inch wide, remained undetected in the orbit for many weeks.

THE OUTBREAK OF DIPHTHERIA AT THE LAMBETH PAROCHIAL SCHOOLS.

WE have received a pamphlet with the title, "History of a Diphtheria Outbreak at the Lambeth Parochial Schools, West Norwood, May to July, 1905," by Dr. Joseph Priestley, medical officer of health of the metropolitan borough of Lambeth. The report is a most interesting one and contains many observations well worthy of note. An outbreak of diphtheria occurred during May, June, and July, 1905, amongst the children at the Lambeth Parochial Schools, situated in Elder-road, West Norwood. The majority of the cases were of a mild (chiefly nasal) type, which naturally gave rise to difficulties, not only in diagnosis but also in the adoption of the usual preventive measures. The slightness, and in some cases the apparent absence, of the well-known clinical symptoms of diphtheria rendered it necessary to carry out minute and careful bacteriological examinations both of "suspects" and of "contacts." These investigations were all carried out in the borough laboratory and reflect great credit on the workers in that institution. Of special interest was the presence in the throats and noses of some of the patients of a mixed infection—viz., (*a*) Vincent's organisms, in addition to (*b*) Hoffmann's pseudo diphtheria bacilli; and (*c*) Klebs-Löffler diphtheria bacilli. By means of the presence in some of the cases of these Vincent's organisms the source of the outbreak was definitely traced. We may remind our readers that Vincent's organisms consist (1) of fusiform elongated bacilli varying in length from 6 to 12 μ and from 1 to 1·5 μ in breadth, vacuolated, motile or non-motile, not staining with Gram's fluid but staining irregularly with Ziehl's liquid; and (2) fine long spirilla of varying lengths, sinuous and very motile, staining badly (or not at all) with the usual staining fluids. By permission of Professor H. Vincent a good illustration of these organisms has been inserted in the report. The presence of Vincent's organisms was due to a concurrent attack or outbreak of either ulcerative stomatitis or the ulcerative form of Vincent's angina, which occurred at (and about) the time of the diphtheria outbreak. In THE LANCET of July 16th, 1904, p. 135, we published a paper by Dr. H. W. Bruce on this affection, who pointed out that the disease was of importance because it was very likely to be mistaken for diphtheria. In THE LANCET of May 13th, 1905, p. 1260, will be found an article upon Vincent's angina from the pen of Professor Vincent himself. From this description it will be seen that it is a disease allied to diphtheria and other forms of throat troubles and appears at times to be contagious, spreading from person to person, either by direct contact or indirectly through the use of towels, drinking utensils, and *so on*. The *disease exists* in two forms: (1) diphtheroid (like diphtheria) or (2) ulceromembranous (deep ulcerations of the membranes over the tonsils and palate). It may appear at any age but is especially frequent amongst children from eight to ten years and amongst young adults from 18 to 30 years of age. Its occurrence at the time of the outbreak of diphtheria at the Lambeth *schools is of great* interest and demonstrates the value of careful bacteriological *examinations*. Dr. Priestley gives a good account of the details of the outbreak of diphtheria and of the means which were taken to check its *spread*. Many patients were found who appeared to have no clinical symptoms of diphtheria but in whose throats or noses (or both) the pathogenic bacillus was found. These individuals were capable of conveying the disease to others, but there was a timidity in removing them to the Metropolitan *Asylums Board* hospitals. Dr. Priestley mentions that the difficulties were added to by the doubt in the minds of some of the guardians as to the value of the bacteriological examinations. We trust that by now they have been fully convinced and that their doubts have vanished. We congratulate *Dr. Priestley* on the completeness of his report.

BRONCHO-PNEUMONIA DUE TO THE BACILLUS OF FRIEDLÄNDER.

THE bacillus of Friedländer is one of the organisms which produce pneumomia, but since Fraenkel's discovery that the pneumococcus is the usual cause of pneumonia the former organism has received little attention *from* clinicians or pathologists. In the *Archives Générales de Médecine* of July 10th M. Lucien Rivet has reported the following interesting case. A man, aged 63 years, was admitted into hospital under *the* care of Dr. Chauffard on June 5th, 1905. He had been *suddenly* taken ill on June 1st with acute pain below the right breast, which was followed by a severe and prolonged rigor. *At* the same *time there* appeared a *dry* and "*tearing*" cough and high fever.

From the beginning there was bloody expectoration. On admission intense dyspnœa was present, the face was cyanosed, the respirations were 40 and shallow, the skin generally was bluish, and the eyes were bright and injected. The upper half of the right chest was absolutely dull, the vocal fremitus was abolished, and there was tubular breathing. In the axilla crepitant rales were heard. In the rest of the chest there were scattered sibilant râles. The sputum was very viscid and adherent and definitely bloody. The pulse was 130 and good. The urine was scanty and contained a little albumin. The temperature was 103·6° F. The sputum contained the pneumo-bacillus of Friedländer in pure culture. The bacillus was strongly coloured by methylene blue and did not retain Gram's stain. On the 7th the temperature was 103·1°, the pulse became thready and uncountable, and the patient died. The necropsy showed hepatisation of the upper lobe of the right lung, which was of a violaceous red colour, finely granular appearance, and friable. The middle lobe was in a state of atelectasis and the lower lobe appeared normal. In the upper lobe of the left lung there was one focus of hepatisation and in the lower lobe four foci. These foci were of the same appearance as the hepatised mass on the right side but much smaller, varying from the size of a walnut to that of a mandarin orange. The heart was fatty and there were some small calcareous patches on the aorta. The kidneys were much congested. The hepatised lung and spleen contained the bacillus of Friedländer in pure culture. Sections of the hepatised lung, both of the large mass in the right lung and the smaller foci in the left, showed the characteristic changes of pneumonia—fibrinous exudation containing desquamated epithelium and numerous leucocytes, particularly polynuclear ones. In places the blood-vessels were much dilated, forming veritable lakes of blood. In all the lesions were numerous bacilli of Friedländer. The liver was very fatty and slightly cirrhotic and showed some nodules containing the pneumo-bacillus. The cortex of the kidneys contained the bacillus both in an isolated form and in little colonies. The spleen also contained colonies and hæmorrhagic foci. M. Netter has pointed out the importance of the pneumo-bacillus in the production of broncho-pneumonia. Some writers insist on the extreme gravity of pneumonia and broncho-pneumonia when this organism is present. According to M. Netter the sputum is still more viscid than in ordinary pneumonia and in four out of five of his cases it was rusty, being greyish in the remaining one. In the present case it was more than rusty—it was distinctly hæmorrhagic. The pneumo-bacillus seems prone to produce hæmorrhagic lesions. Fatal cases of hæmorrhagic septicæmia due to it have been recorded and this disease has been produced in the rabbit by inoculation. It is noteworthy that the gravity of the case described above was not due merely to the pulmonary lesions but that there was a general infection with the pneumo-bacillus. Such a general infection is now well known to occur in the ordinary pneumonia due to the pneumococcus.

THE STERILISATION OF CATGUT BY MEANS OF BENZINE.

Dr. Kendirdjy has recorded in the *Répertoire de Pharmacie* of July 10th the results of an investigation of the various methods employed for the sterilisation of catgut, and he confirms the work of M. Beslier,[1] who found the vapour of benzine to give more satisfactory results than alcohol or acetone. Dr. Kendirdjy states, however, that one sterilisation is not sufficient, as he has obtained cultures of the bacillus subtilis from catgut which had been once sterilised with benzine. He thinks that the process should be repeated five times. His modification of the method consists in heating the catgut in the vapour of crystallisable benzine at a temperature of from 120° to 130° C. for one hour on five successive days. The vapour of benzine does not affect the solidity or the suppleness of the catgut and, when applied as directed, completely destroys the spores of the bacillus subtilis and all other micro organisms.

PROFESSOR Ivan Petrovitsch Pawlow, professor of physiology in the University of St. Petersburg, will open the winter session of the medical school at Charing Cross Hospital on Monday, Oct. 1st, and deliver the sixth biennial Huxley lecture "On Recent Advances in Science and their Bearing on Medicine and Surgery," at 4 P.M. Medical practitioners desiring to attend can obtain cards of admission on application to the Dean so far as the accommodation goes.

WE are informed that Dr. Frederick Taylor, the senior physician to Guy's Hospital, and Dr. E. G. Graham Little, physician for diseases of the skin at St. Mary's Hospital, are standing as candidates for the vacancy which has arisen, owing to the resignation of Dr. J. F. Payne, among the members of the Senate of the University of London representing convocation.

THE death of Dr. J. H. Bell of Bradford is announced at the age of 74 years. Dr. Bell was well known in the medical profession for his studies in the subject of anthrax. We hope to give an extended account of his career in a future issue.

THE session at St. Thomas's Hospital will commence on Oct. 3rd, and the Old Students' dinner will be held at the Hotel Cecil on the previous evening at 7 for 7.30 P.M., when Dr. Arthur Newsholme will preside.

A TELEGRAM from the Acting Governor of the Mauritius received at the Colonial Office on Sept. 7th states that during the fortnight ended on Sept. 6th there were 13 cases of plague, all of which proved fatal.

MEAT INSPECTION IN BELFAST.

THE honorary secretary of the Belfast Provision Curers' Association has issued and sent to the members of the Belfast corporation an important document on the question of meat inspection, especially in reference to pork. He points out that he knows of no evidence based on statistics taken in Ireland which would support the theory put forward by the 1898 Royal Commission on Tuberculosis (Sir Herbert Maxwell's Commission), in which it is stated that "in view of the greater tendency to generalisation of tuberculosis in the pig, we consider that the presence of tubercular deposit in any degree should involve seizure of the whole carcass and the organs." This has not been verified by actual inspection of swine in the North of Ireland, and the experience of the local provision trade is entirely against it. It is noteworthy that while pig-raising is a most important industry in Ireland, yet when it comes to the selection of a Royal Commission to devise practical measures for the control of tuberculosis in the meat-supply not a single representative from Ireland is appointed, nor, indeed, anyone with any practical acquaintance with the provision curing trade. It is a pity that this was so, as the omission has evidently left a feeling of soreness. The report of the secretary of the Belfast Provision Curers' Association goes on to point out that it is very remarkable that the Royal Commission made a distinction between tuberculous pigs and tuberculous cattle, recommending that in the case of cattle the carcass, if otherwise healthy, should not be "condemned" but only such part of it as contained tuberculous lesions, and only in case of advanced tuberculosis was the entire carcass of cattle to be destroyed. This distinction, the association affirms, is not recognised in the practice of other countries, pigs and cattle being treated alike.

---

[1] See THE LANCET, Sept. 15th, 1906, p. [illegible]

The report urges that much has been learned with regard to tuberculosis since 1898, the date of Sir Herbert Maxwell's Commission. A Committee of the House of Commons took evidence in connexion with the Tuberculosis (Animals) Compensation Bill (1904), and of all the witnesses who gave evidence in 1904 not one supported the recommendations of the Maxwell Commission as regards pigs. Professor Matthew Hay of Aberdeen stated that only two pigs out of 2000 slaughtered in the previous year in that city were condemned. It is obvious that Aberdeen, in the case of the pig, does not follow the recommendation of the Royal Commission. Before the same Committee Dr. R S. Marsden of Birkenhead, in reply to the question "Do you as a scientific man say that an animal with even the smallest amount of tubercle can be fit for human food or as fit as an animal that has not tuberculosis at all?" answered: "Yes, I think so. I think to some extent there was exaggeration in the minds of some of us when we originally began. I think if the dangers were as great as at first supposed there would have been far greater evils than have occurred. Therefore, I do not think it right to condemn on the merest speck of tubercle a whole carcass. I think it a matter in which a man must use common sense as well as scientific knowledge, and I lay great stress on common sense." Mr. J. King, veterinary inspector for the Corporation of London, stated "as his own personal view, with his experience of many years, that Sir Herbert Maxwell's Commission was too hard upon the pig." "Pigs," he added, "ought to be dealt with in the same way as cattle—that is to say, that tuberculosis should be treated as a localised disease." The superintendent of the Birmingham corporation markets (Mr. F. H. Edwards) stated that in Birmingham out of 175,000 pigs slaughtered the number of condemnations was 291. The Birmingham authorities did not follow, he said, the recommendations of the Royal Commission (Sir Herbert Maxwell's) in the case of pigs. "We do not," he said, "condemn the whole carcass where it is a mere local affection with regard to pigs." The chairman of the health committee of the corporation of Glasgow, Baillie Anderson, J.P., submitted statistics to show that during 1905 53,483 swine were slaughtered in Glasgow. Of these 2132 were found to be affected with tuberculosis, 152 were subsequently passed, 75 were totally destroyed, while 1905 pigs were partially destroyed (heads only), the remainder of the carcass being handed back to the owner. Under the Belfast system of inspection, where there is no classification as to the degree of tuberculosis, instead of 75 pigs being totally destroyed, as in Glasgow, there would have been 2132. Baillie Anderson informed the committee that the Glasgow inspection "was not quite so stringent as the Commission on Tuberculosis recommended in the case of pigs." All this evidence, which has accumulated since Sir Herbert Maxwell's Commission sat, ought, the Belfast Provision Curers' Association thinks, to receive proper attention.

The secretary of the association next submits an actual test carried out on four pigs bought in Cookstown market on July 7th, 1906, and condemned by the inspector of the Belfast corporation to total destruction as being unfit for food. These were carefully examined by Professor W. St. Clair Symmers of Queen's College, Belfast. Three of the animals showed tuberculous changes in certain of the neck glands and the fourth did not contain any tuberculous glands at the time he saw it. Neither by the naked eye nor microscopically could Professor Symmers detect evidence of tuberculosis in the flesh of these animals, nor in the juices obtained from the flesh by the most rigorous method known to bacteriologists. He says in his report: "I conclude that the flesh of these four animals was free from tuberculous germs, that the tubercle was limited to the neck glands, and that the destruction of the non-tuberculous portions of the carcass was unnecessary. I may add that proper cooking will easily destroy any tuberculous germs if such should happen to be present, but in the flesh (as distinct from the glands) of the four pigs here in question there were no tubercles to be destroyed."

Reference in the report is then made to the measures adopted in Germany to protect the meat-supply and Professor Ostertag, of the Veterinary High School at Berlin, is quoted as stating in his "Handbook of Meat Inspection" that "at present the view is generally entertained that in undoubted cases of local tuberculosis the meat is harmless, while in generalised cases it is harmful," and that "the assumption of the harmlessness of meat in cases of undoubted local tuberculosis will probably remain for all time as an immutable dogma of meat inspection." This is the view which the Belfast Provision Curers' Association ask, the Belfast corporation to adopt, in line with the practice of the great English cities mentioned and with Germany itself, where the most severe restrictions are in force in order to protect a population that eats uncooked meat. Professor MacFadyean is quoted as saying before the Royal Commission of 1896: "I feel quite satisfied that if tuberculosis were absolutely eradicated from the cattle of this country it could not sensibly affect the percentage of tuberculosis among human beings." And, again: "I doubt whether there are ten people in this country in the year who contract tuberculosis through meat; I think even one might doubt whether there is one." Again, Sir Charles Cameron stated before the same Royal Commissioners: "If I were put into the witness-box I would not be able to swear I ever knew anyone who got tuberculosis from either meat or milk, and there are few people who could do so." In Prussia during 1902 (latest statistics available) there were slaughtered 3,909,778 pigs; of these 103,192 were found to be tuberculous but only 4604 were condemned to total destruction. The carcases of 93,825 were allowed to be sold after removal of affected organs and tissues. Under our Belfast system the whole 103,192 carcasses would have been totally destroyed. If the farmers and pig feeders of Prussia alone had been subject to the meat inspection rules of Belfast their loss from pork destroyed, calculated at present prices, would have been £380,000 to £400,000 per annum over and above what their highly-trained inspectors actually found necessary to condemn, though taking measures to protect the food-supply of a people accustomed to eat pork in large quantities absolutely uncooked. Why in Belfast, where the population uniformly cook their ham and bacon, should precautions be used to a degree beyond anything conceived in Germany?

An extract from the regulations governing the meat inspection of the United States Department of Agriculture, dated June 30th, 1906, is published as an appendix to the pamphlet. It runs as follows:—

Tuberculosis.—All carcasses affected with tuberculosis and showing emaciation shall be condemned. All other carcasses affected with tuberculosis shall be condemned, except those in which the lesions are slight, calcified, or encapsulated, and are confined to the tissues indicated in any one of the following five paragraphs, or to a less number of such tissues and excepting also those which may under Paragraphs (6) and (7) below, be rendered into lard or tallow. 1. The cervical lymphatic glands and two groups of visceral lymphatic glands in a single body cavity, such as the cervical, bronchial, and mediastinal glands or the cervical, hepatic, and mesenteric glands. 2. The cervical lymphatic glands and one group of visceral lymphatic glands and one organ in a single body cavity, such as the cervical and bronchial glands and the lungs, or the cervical and hepatic glands and the liver. 3. Two groups of visceral lymphatic glands and one organ in a single body cavity, such as the bronchial and mediastinal glands and the lungs, or the hepatic and mesenteric glands and the liver. 4. The cervical lymphatic glands and one group of visceral lymphatic glands in each body cavity, such as the cervical, bronchial, and hepatic glands. 5. Two groups of visceral lymphatic glands in the thoracic cavity, and one group in the abdominal cavity, or one group of visceral lymphatic glands in the thoracic cavity and two groups in the abdominal cavity, such as the bronchial, mediastinal, and hepatic glands, or the bronchial, hepatic, and mesenteric glands. 6. Carcasses affected with tuberculosis in which the lesions of the disease are located, as described in any one of the preceding five paragraphs, but are slight and in a state of caseation or liquefaction necrosis, or surrounded by hyperæmic zones, and also those in which slight, calcified, or encapsulated lesions are found in more visceral organs or more groups of visceral lymphatic glands than are specified in any one of the preceding five paragraphs, may be rendered into lard or tallow, after the diseased parts are removed. The carcasses shall be cooked by steam at a temperature not lower than 220° F. for not less than four hours. 7. Carcasses in which the cervical lymphatic glands, one organ, and the serous membrane in a single body cavity, such as the cervical lymphatic glands, the lungs, and the pleura or the cervical lymphatic glands, the liver, and the peritoneum, are affected with tuberculosis may be rendered into lard or tallow, after the diseased parts are removed. The carcasses shall be cooked by steam at a temperature not lower than 220° F. for not less than four hours. 8. All condemned carcasses, parts of carcasses, or organs showing lesions of tuberculosis shall be deposited in receptacles provided for that purpose and shall either be tanked at once or be locked in the "condemned" room until such time as an employee of the department can see that they are placed in the tank. 9. All heads and other parts showing lesions of tuberculosis shall be condemned.

The secretary of the Belfast Provision Curers' Association certainly makes out a strong case for asking that the meat regulations of Belfast shall be in conformity with the requirements dictated by scientific authority and prevalent elsewhere.

ON Sept. 1st Dr. T. H. S. Pullin completed 50 years' service as medical officer of the Sidmouth district of the Honiton (Devon) union.

MEDICINE AND THE LAW.

Are Honorary Medical Officers Entitled to Fees for Giving Evidence?

Is an honorary medical officer to a public hospital who has attended upon a deceased person entitled to a fee for attending an inquest touching the death of such deceased person or for making a post-mortem examination made at the request of the coroner? The matter is regulated to a great extent by Section 22 of the Coroners Act, 1887. That section prescribes the fees that are to be paid to medical witnesses. It enacts as follows:—"A legally qualified medical practitioner who has attended at a coroner's inquest in obedience to a summons of the coroner under this Act shall be entitled to receive such remuneration as follows; that is to say, (*a*) for attending to give evidence at any inquest whereat no post-mortem examination has been made by such practitioner, one guinea; and (*b*) for making a post-mortem examination of the body of the deceased, with or without an analysis of the contents of the stomach or intestines, and for attending to give evidence thereon, two guineas. Provided that—(1) any fee or remuneration shall not be paid to a medical practitioner for the performance of a post-mortem examination instituted without the previous direction of the coroner; (2) where an inquest is held on the body of a person who has died in a county or other lunatic asylum or in a public hospital, infirmary, or other medical institution, or in a building or place belonging thereto or used for the reception of the patients thereof, whether the same be supported by endowments or by voluntary subscriptions, the medical officer whose duty it may have been to attend the deceased person as a medical officer of such institution as aforesaid shall not be entitled to such fee or remuneration." This section does not define very clearly the institutions to which it is intended to apply. It has been held by a county-court judge that the sick wards of a workhouse are within the terms of the enactment, but among other institutions such as prisons, military hospitals, public schools, training colleges, almshouses and asylums for the aged, dispensaries, cottage hospitals, and nurses' homes, doubts may well arise as to whether the medical officer is entitled to claim any fees. In the not infrequent case of an accident happening in the street and death resulting before the body reaches the public hospital to which it is being carried, the medical officer of the hospital may be summoned under Section 21, Subsection (1) as an expert to give his opinion as to the cause of death, and in such case he would be entitled to the usual fee. Section 23 enacts that "where a medical practitioner fails to obey a summons of a coroner issued in pursuance of this Act, he shall, unless he shows a good and sufficient cause for not having obeyed the same, be liable on summary conviction on the prosecution of the coroner or of any two of the jury to a fine not exceeding £5." It does not appear whether this section is intended to be in addition to, or in substitution for, the powers conferred by Section 19. It would seem that the provisions of Section 19 are wide enough to cover medical practitioners; and, if so, the trouble and inconvenience of instituting a prosecution in which the decision as to the necessity of summoning the medical practitioner would rest with the justices instead of with the coroner would practically make this section a dead-letter. Subsection 2 of Section 19 of the Coroners Act enacts that "when a person duly summoned to give evidence at an inquest does not, after being openly called three times, appear to such summons, or appearing, refuses without lawful excuse to answer a question put to him, the coroner may impose on such person a fine not exceeding 40*s*." Subsection 3: "Any power by this Act vested in a coroner of imposing a fine on a juror or witness shall be deemed to be in addition to and not in derogation of any power the coroner may possess independently of this Act for compelling any person to appear and give evidence before him on any inquest or other proceeding, or for punishing any person for contempt of court in not so appearing and giving evidence, with this qualification, that a person shall not be fined by the coroner under this Act and also be punished under the powers of a coroner independently of this Act." The coroner has power to compel the attendance of a witness by summons and in case of disobedience to issue a warrant to cause him to be apprehended and brought into court, but it does not appear that there is any means provided for executing such a warrant outside the coroner's jurisdiction. In Horner *v.* Lewis (62 J.P. 345) the appellant's claim was for 2 guineas, fees alleged to be due to him under the Coroners Act, 1887, Section 22, for making a post-mortem examination by order of the respondent, the coroner for the county. The facts were as follows. The appellant was honorary medical officer to the Wanstead Children's and General Hospital and received no remuneration for attending the patients therein by way of fees, honorarium, or otherwise. He attended on the deceased child while a patient in the hospital and by order of the respondent, the coroner, made a post-mortem examination and attended the inquest under a subpœna and gave evidence as to the condition of the child when she was taken into the hospital and as to the cause of death as ascertained by means of the post-mortem examination. He applied for the fees due to him for such attendance and making the examination, but the coroner refused to pay, alleging that by the Coroners Act, 1887, Section 22, Subsections 1 and 2, the appellant was not entitled to such fees. The action was a friendly one and was brought to obtain a decision on the question in order that if the fees were payable the coroner might obtain payment from the county council. The county-court judge decided against the appellant's claim. The appeal came before Mr. Justice Wills and Mr. Justice Kennedy, sitting as a Divisional Court. Mr. Justice Wills in the course of his judgment said: "The question here is not whether one likes or dislikes the effect of the Act of Parliament which we have to interpret. I may sympathise with medical men who are made to perform duties without receiving payment for them but that cannot affect my decision. The simple point is whether this particular case falls within the Act of Parliament. It is impossible to say that this institution is not a public hospital. I shall not attempt any definition of what is a public hospital, but I think it is easy to say whether a case is one side of the line or not. In connexion with this hospital there is a published list of governors and subscribers; there are the names of a medical staff, annual meetings are held, patients are admitted by governors' letters, and all the other elements are present which are found in any of the great London hospitals, which no one would deny are undoubtedly public. Then, it is argued that the patients of this hospital are restricted to the inhabitants of a certain area and to people who can get letters from governors, but these are circumstances which are found in many great hospitals which are undoubtedly public. The next question we have to consider is whether the appellant is 'the medical officer of such institution whose duty it was to have attended on the deceased as a medical officer of such institution.' It is said that he is not because he is not paid for any of his services and that the word 'duty' can only mean that he is legally bound to attend the patients. I think it does not mean only paid duty, but that it refers to a medical officer who is within his function in attending on a patient in the institution. The appellant figures in the published list of medical officers. It is not at all unusual to find unpaid officers in London hospitals, because gentlemen perform such services gratuitously for the sake of advantages which may accrue to them in the way of experience or otherwise. It is argued that even if the appellant was the medical officer there was no 'duty' on him to attend the deceased. It is clearly his duty, though it was true it was a duty of imperfect obligation. That duty brought him within the section, and the case therefore falls under the proviso of the Act of Parliament." Therefore, so long as this decision stands honorary medical officers who may have attended a patient in a hospital or made a post-mortem examination on the direction of the coroner, are bound to attend his court and to give their evidence without fee or reward. We are strongly of opinion, however, that the law should be altered.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 76 of the largest English towns 8350 births and 6754 deaths were registered during the week ending Sept. 8th. The annual rate of mortality in these towns, which had been equal to 18·4 and 18·3 per 1000 in the two preceding weeks rose last week to 22·3, a considerably higher rate than had prevailed in any previous week of this year.

During the first ten weeks of the current quarter the death-rate in these towns averaged 15 3 per 1000, the rate during the same period in London being 15·0 The lowest death-rates in the 76 towns during the week were 8 4 in Hornsey, 10·8 in King's Norton, 12·8 in West Hartlepool, and 13·1 in South Shields; the rates in the other towns ranged upwards to 31·4 in Hanley, 31 5 in St. Helens, 32·0 in Merthyr Tydfil, 32 8 in Coventry, and 33·8 in Grimsby. The 6754 deaths in the 76 towns showed an increase of 198 upon the number returned in the previous week, and included no fewer than 2571 which were referred to the principal epidemic diseases, against numbers increasing from 362 to 1978 in the eight preceding weeks; of these, so many as 2342 resulted from diarrhœa, while 65 were referred to measles, 60 to whooping cough, 42 to diphtheria, 37 to "fever" (principally enteric), 24 to scarlet fever, and one to small-pox. The deaths from these epidemic diseases were equal to an annual rate of 8 5 per 1000 in the 76 towns and to 6·4 in London. These epidemic diseases caused no death in Hornsey and the annual rate therefrom did not exceed 1·0 in Halifax and 1·4 in King's Norton; whereas it ranged upwards to 16·7 in Stockport, 17 4 in Bootle, 18·1 in Hanley, and 23·2 in Coventry. The deaths referred to diarrhœa (mainly of infants under one year), which had steadily increased in the 13 preceding weeks from 50 to 1765, further rose during the week under notice to 2342; the highest annual rates from this disease during the week were 15 0 in Bootle, 16·1 in Preston, 17·3 in Hanley, and 22 5 in Coventry. The largest proportional mortality from measles occurred in Huddersfield, Bury, Stockport, and Rotherham; from whooping cough in Swansea and Middlesbrough; and from diphtheria in Aston Manor and Smethwick. Six deaths were referred to "fever" in Hull, three in Leeds, and two each in Liverpool, Bristol, and Aston Manor. Scarlet fever caused two deaths in East Ham, Birkenhead, Salford, and Sheffield. The fatal case of small-pox occurred in Devonport. No case of small-pox was under treatment in the Metropolitan Asylums hospitals during the week, no new case having been admitted thereto since the end of June. The number of scarlet fever cases under treatment in the Metropolitan Asylums hospitals and in the London Fever Hospital, which had been 3078 and 3042 at the end of the two preceding weeks, rose again to 3067 during the week under notice; 415 new cases were admitted to these hospitals during the week, against 350, and 317 in the two preceding weeks The deaths referred to pneumonia and other diseases of the respiratory organs in London, which had been 103 and 109 in the two previous weeks, further rose last week to 143, and exceeded by 13 the corrected average in the corresponding week of the four preceding years, 1902–05 The causes of 42, or 0·6 per cent., of the deaths registered in the 76 towns during the week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Manchester, Leeds, Salford, Bristol, Hull, and in 48 smaller towns; the proportion of uncertified causes showed, however, a considerable excess in Reading, Wigan, Bolton, Rochdale, and Bradford.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in eight of the principal Scotch towns, which had been 13·8 and 14·2 per 1000 in the two preceding weeks, further rose to 15 8 in the week ending Sept. 8th but was no less than 6 7 below the mean rate in the same week in the 76 English towns. The rates in the eight Scotch towns ranged from 9 0 and 12·6 in Paisley and Leith to 17·1 in Dundee and in Aberdeen and 19·2 in Greenock. The 533 deaths in the eight towns showed a further increase of 46 upon the numbers returned in the two previous weeks, and included 85 which were referred to the principal epidemic diseases, against 79 and 80 in the two preceding weeks. These 85 deaths were equal to an annual rate of 2·5 per 1000, which was no less than 6 0 below the rate from the same diseases in the 76 English towns Of these 85 deaths, 62 resulted from diarrhœa, eight from "fever," seven from whooping-cough, four from scarlet fever, two from measles, two from diphtheria, and not one from small-pox. The deaths referred to diarrhœa in the Scotch towns, which had been 54 and 48 in the two previous weeks, rose last week to 62, and exceeded the number in any previous week of this year; they included 31 in Glasgow, 10 in Dundee, nine in Edinburgh, six in Greenock, and four in Aberdeen. Seven of the eight deaths referred to "fever" were returned in Glasgow and included three certified as cerebro-spinal meningitis. The two fatal cases of measles, three of the four of scarlet fever, as well as five of the seven deaths from whooping-cough, were also returned in Glasgow. Diphtheria caused one death both in Dundee and Aberdeen. The deaths in the eight towns referred to diseases of the respiratory organs, including pneumonia, which had been 52 and 61 in the two preceding weeks, declined again to 50 in the week under notice, and were 10 below the number returned in the corresponding week of last year. The causes of 11, or 2·1 per cent., of the deaths registered during the week were not certified; the mean proportion of uncertified deaths in the 76 English towns did not exceed 0 6 per cent.

HEALTH OF DUBLIN.

The annual death-rate in Dublin, which had steadily increased from 16 8 to 21·9 per 1000 in the five preceding weeks, further rose to 24·1 during the week ending Sept. 8th. During the first ten weeks of the current quarter the death-rate in the city averaged 19·8 per 1000 the mean death rate during the same period being only 15 0 in London and 12·3 in Edinburgh. The 175 deaths of Dublin residents during the week under notice showed a further increase of 16 upon the numbers returned in the five preceding weeks, and included 52 which were referred to the principal epidemic diseases, against 27 and 28 in the two previous weeks; these 52 deaths were equal to an annual rate of 7·2 per 1000, the death-rate during the week from the same diseases being 6·4 in London and only 1·8 in Edinburgh. Of these 52 deaths no fewer than 49 were referred to diarrhœa (against 27 in each of the two preceding weeks), two to "fever," one to whooping-cough, and not one either to small-pox, measles, scarlet fever, or diphtheria. The deaths of infants showed a marked increase on the numbers returned in recent weeks, while those of elderly persons had declined. Nine inquest cases and five deaths from violence were registered; and 54, or 30·9 per cent, of the deaths occurred in public institutions. The causes of all but one of the deaths registered during the week were duly certified.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments are notified:—Fleet Surgeons: G. T. Broatch to the *President*, for three months' course at West London Hospital; J. H. Beattie to the *Dryad*, for Navigation Schools; W. Bowden, D.S.O., to the *Formidable* on recommissioning; A. MacLean to the *Ganges* for *Ganges II.*; E. R Dimsey, D.S.O., to Cape Hospital; J. H Whelan to the *Vernon*; and G. Hewlett to the *Barfleur*. Staff Surgeon H. J. Chater to the *President*, additional, for three months' course at West London Hospital. Surgeons: F. R. Mann to the *President*, for three months' course at Middlesex Hospital; E T. Burton to the *Victory*; A. K. Smith Shand to the *Formidable*, on recommissioning; and J. Thornhill to Royal Marines at Portsmouth.

In accordance with the provisions of Her late Majesty's Order in Council of April 1st, 1881, Surgeon M. Breton has been placed on the Retired List. Fleet Surgeon F. W. Stericker has been placed on the Retired List at his own request.

ROYAL ARMY MEDICAL CORPS.

Lieutenant Colonel Richard W. Ford, D.S.O., from the Seconded List, to be Lieutenant-Colonel (dated August 17th, 1906). Lieutenant-Colonel Reginald J. C. Cottell is seconded whilst holding the appointment of Deputy Surgeon, Royal Hospital, Chelsea (dated August 17th, 1906). Captain Thomas J. Crean, V C., retires, receiving a gratuity (dated Sept. 8th, 1906). Lieutenant John H. Spencer is seconded under the provisions of Article 349, Royal Warrant, March 19th, 1906 (dated July 31st, 1906). Lieutenant-Colonel Richard F. O'Brien retires on retired pay (dated Sept. 12th, 1906). Lieutenant-Colonel G. G. Adams has been appointed Medical Inspector of Recruits in the Southern Command. Lieutenant-Colonel H. G Hathaway, who was dangerously wounded at Diamond Hill, South Africa, on June 11th, 1900, has been awarded a permanent wound pension.

The medical officers at the Aldershot Army Corps manœuvres on the South Downs are as follows:—Army Corps Staff: Principal medical officer, Surgeon-General Sir Thomas Gallwey, A.M.S.; staff officer to the principal medical officer, Lieutenant-Colonel T. W. O'H. Hamilton, C.M.G. The principal medical officers of the First, Second, and Third Divisions of the Blue Force are respectively Lieutenant-Colonel H. N. Thompson, D.S.O., Major H. I. Pocock, and Major Frederick Smith, D.S.O.

Army Medical Reserve of Officers.

Surgeon-Lieutenant-Colonel John H. Maclean having resigned his commission in the Volunteers, ceases to belong to the Army Medical Reserve of Officers.

Volunteer Corps.

Royal Garrison Artillery (Volunteers): 2nd Middlesex: Surgeon-Captain A. B. Lyon to be Surgeon-Major (dated August 20th, 1906). 2nd Middlesex: Surgeon-Lieutenant-Colonel (Honorary Captain in the Army) A. Thorne is granted the honorary rank of Surgeon-Colonel (dated August 27th, 1906).

Rifle: 1st Volunteer Battalion the Prince Albert's (Somersetshire Light Infantry): Surgeon-Captain J. M. Harper to be Surgeon-Major (dated August 1st, 1902).

Deaths in the Services.

Deputy Inspector-General of Hospitals and Fleets Richard Dormer White on August 26th at Victoria Hospital, Folkestone, aged 61 years. He graduated as M.B. at the University of Dublin in 1871 and proceeded to the degree of M.D. in 1881. He entered the navy as surgeon in April, 1873, being promoted staff surgeon in April, 1885, and fleet-surgeon in October, 1893, retiring with the honorary rank of deputy inspector-general of hospitals and fleets in August, 1902. He was fleet surgeon of the *Raleigh* and served in the Naval Brigade landed from that vessel and others at Bathurst, on the River Gambia, West Coast of Africa, in February, 1894, for the punishment of a rebellious slave-raider chief. For his services with this expedition, in which he was slightly wounded, he was mentioned in despatches, was nominated for the C.B., and received the medal with Gambia, 1904, clasp. He received the thanks of the Admiralty for services in the *Cambridge* in 1873 and the thanks of the Medical Director-General for the journal of the *Bullfrog* when serving on the West Coast of Africa in 1884–85. He also served with Lord Sackville in exploring the water-sheds of the river Pilcomayo on the borders of Bolivia and Paraguay in South America.

Brigade-Surgeon Charles Frederick Richards on August 30th at Rathturret, Warrenpoint, county Down, aged 67 years. He graduated as M.B. at the University of Dublin in 1865 and entered the army as an assistant surgeon in October, 1866, being promoted surgeon in March, 1873, and surgeon-major in January, 1879, retiring with the honorary rank of brigade-surgeon in August, 1888.

The "Spectator" Experimental Company.

We cordially congratulate the *Spectator* on its Experimental Company and on the result it has achieved in showing that young men can be sufficiently drilled and trained in the course of six months to become efficient soldiers. Nor must it be forgotten that in point of health, physique, intelligence, and alertness of mind the men are not what they were when they first joined the company to undergo a voluntary course of military training; they are all round better. This country will always *need* to have a regular army of highly trained and disciplined troops, and a perfect soldier cannot be turned out with the accumulated experience of a veteran in the course of six months; but the elements of military training *can* be acquired in the brief time named, and once acquired will not be forgotten. It now remains to be ascertained what is the minimum of periodical training practically required to maintain what has been gained.

Soldiers' Foul Water bottles.

It is notified in the Northern Command that water-bottles in such a state as to be liable to cause sickness have been found in possession of regulars, militia, yeomanry, and volunteers. Commanding officers are ordered to have all water-bottles thoroughly cleansed by scalding with boiling water, also all water carts and bottles in the Army Ordinance Department charge are to be disinfected.

Lord Kitchener has instituted a system of lectures on sanitation, to be delivered during the cold season in every military station in India by specially selected medical officers.

Correspondence.

"Audi alteram partem."

OPERATIVE TREATMENT IN CERTAIN CASES OF INSANITY.

To the Editors of THE LANCET.

SIRS,—Your correspondent, "M.R.C.S.," does well to raise the question of operative interference in one of his cases which apparently has resisted other means of treatment. I have for some years maintained the advantage of early surgical interference to relieve pressure and the necessary consequence of it—viz., wasting of the cells and disturbance of the circulation. I have also recorded cases where relief has followed operation and I have indicated in papers read before the Medico-Psychological Society, the forms of central disease in which surgical measures are to be recommended. My experience has been limited to the removal of bone but I can well understand that direct diminution of the blood-supply by ligature of a vessel is worthy of consideration. The risk of tying the carotid artery is that the sudden arrest of such a large supply of blood to one side of the brain may cause paralysis from softening and that if the patient is troublesome the after-treatment might be attended with difficulties. I have in some cases employed venesection with advantage and though the patients have occasionally tried to interfere with the bandages the difficulty has been overcome by constant supervision until the wound healed, but the possibility of difficulty in this direction should be carefully estimated before interfering with such a large vessel as the carotid artery. So much depends upon the acuteness of the symptoms that it is not necessary to do more than call attention to what may prove to be a dangerous element in considering the propriety of operation.

In the hands of a capable surgeon the operation of trephining to relieve pressure and cerebral congestion is a safe one and in my experience unattended with dangerous or troublesome consequences, and in addition it gives an opportunity of seeing the actual condition of the brain tissue and the membranes, so that an opinion on the prognosis of the case is rendered more reliable, while if desired a drainage of fluid from the congested area can be maintained before the wound is actually closed. It has always seemed to me that the hæmorrhage from the scalp wound in making the primary incision has been very favourable to the object in view, which is to relieve pressure and to prevent permanent destruction of tissue. Operative cranial surgery is, in my opinion, not only justifiable but in well-chosen cases is the only means of scientific treatment, and there is every reason to believe that the early adoption of it would have cured many people who have for want of it proceeded to incurable dementia. The purely medical treatment of insanity has had a long trial and has met with only a partial success. The modern advances in physiology and surgery may well lead us to hope that what has been accomplished with such marked success in the abdomen may be extended to the skull and its contents, for it appears every day to be more certain that in this direction is to be found the remedy for many persons who must otherwise endure the misery of a chronic and hopeless destructive process.

I am, Sirs, yours faithfully,
T. CLAYE SHAW, M.D. Lond., F.R.C.P. Lond.
Harley-street, W., *Sept. 8th, 1906.*

To the Editors of THE LANCET.

SIRS,—The question put by "M.R.C.S., &c." in THE LANCET of Sept. 8th, p. 682, admits of a precise and unhesitating answer. Ligature of the carotid, for the cure or alleviation of mania, would certainly not be justifiable. If it were certain that the mania was not only accompanied, but caused, by hyperæmia of brain, it would still not be justifiable, for the hyperæmia might be of a passive nature which would require not a less vigorous, but a more vigorous *vis a tergo* for its relief; but there is no evidence at all that mania is caused, or even accompanied, by hyperæmia of the brain, and what evidence we have is rather the other way. In cases in which great hyperæmia of the brain is found post mortem, the ante-mortem symptoms are those not of mania, but of coma, and the brains of those who die in acute mania are not often found deeply congested. That anæmia of the brain necessarily follows a diminished supply of blood to the organ, is not quite accurate, for the diminished supply may be more than counterbalanced by a still more diminished efflux; and it is certain that symptoms of mental depression, if by this is meant depression of spirits, or melancholy, do not necessarily follow a diminution in the blood-supply to the brain, for melancholy does not necessarily, nor even usually, follow severe hæmorrhage; nor is it a usual concomitant of general anæmia. "M.R C.S." says that many cases of simple insanity appear to depend almost entirely upon active hyperæmia and increased blood pressure. I usually test by routine the blood pressure of my patients by the sphygmo-hæmometer, and I find that a high blood pressure goes more often with depression of spirits and tranquillity than with excitement; and I would point out that a high pressure of blood in the arteries does not necessarily imply hyperæmia in the tissues, or a more rapid flow of blood through the capillaries. The high pressure may be compensatory, and complementary to some obstruction to the flow of the blood through the small vessels, so that the net result may be a circulation that is not increased, or is even diminished in velocity.

Increased blood pressure may, as "M.R C.S." asserts, be the main cause of the delirium of persons suffering from pyrexia, and of the mental excitement produced by stimulants, and by the administration of ether and chloroform. I know of no series of measurements of blood pressure in these states to give countenance to the assertion that increased blood pressure is present in them; and if it were proved to be uniformly present, proof would still be wanting that the high blood pressure was the cause of the delirium and excitement. To perform on such grounds as this a capital operation, with risk, not only of life, but of permanent damage to brain, even if life is not lost, would be in my opinion unwarrantable. One other statement, made by "M.R.C.S.," as if it were established fact, seems to me open to question. "In cases of mania," he says, "the more acute the symptoms the greater the cerebral disturbance and insomnia, the more favourable is the prognosis." This is not my experience. I am accustomed to teach that the gravity of an attack of acute insanity, by which I mean the danger to life in the first place, and of permanent alienation of mind in the second, is a product of two factors, viz:—the intensity of the attack, and its duration. If by acuteness of symptoms "M.R.C.S." means brevity of the acute attack, I should agree with him; but if, as appears from his context, he means intensity or severity of the attack, then his experience is the reverse of mine.

I am, Sirs, yours faithfully,
CHAS. MERCIER.
Wimpole-street, W., Sept. 8th.

ANÆSTHESIA IN DENTAL SURGERY.

To the Editors of THE LANCET.

SIRS,—In THE LANCET of Sept. 8th I notice a review of the second edition of my little book on the above subject, and while thanking your reviewer for the kind things he has said in regard to it I have pleasure in acceding to his request (or is it a challenge?) and referring him to proof, as far as possible, of the statement made on p. 193 that arrest of the respiration may be due, among other things, to "direct retardation and arrest of the pulmonary circulation, first in the capillaries and then in the larger vessels, due to the local direct action of chloroform."

If your reviewer can get hold of a copy of the "Report of the Discussion on Anæsthetics" of the Glasgow Medico-Chirurgical Society (1891), published by Alex. Macdougall, 81, Buchanan-street, Glasgow, he will find on p. 5 that the late Professor Coats, whose views on the physiological action of chloroform were, I believe, particularly sound, draws attention to this cause of respiratory arrest, basing his remarks on Dr. D. Newman's work when a member of the Glasgow Committee on Anæsthetics. Whether any later observer has confirmed this I am unable to say, but all I wish to contend is that I am not speaking without authority to support me. I have avoided bibliographical references in this book, as I am inclined to think by the average reader they are regarded as a nuisance.

In another journal my remarks on the question of the administration of anæsthetics by a Licentiate in Dental Surgery were dealt with more severely than by your reviewer, the writer evidently regarding me as eminently unsound in this respect. To many London anæsthetists it appears nothing short of heretical to suggest that anæsthetics may be given properly by anyone other than an anæsthetist or "fully qualified medical man." It is, however, perfectly useless to lay down that every man who administers nitrous oxide must be medically qualified. In certain classes of practice it is next to impossible. I live in a country where dentists, until quite recently at all events, even gave chloroform to patients without calling in a medical man. This is, of course, unspeakable and personally I regard the casual administration of ethyl chloride by dentists as only less objectionable. At the same time I would much prefer that patients be given nitrous oxide or mixtures of it with ethyl chloride or ether by a properly trained L.D.S., of whom there are now many about, to their being *chloroformed* by one of my brother M.B.'s. To only too many such anæsthesia still means *chloroform*. I am, Sirs, yours faithfully,

T. D. LUKE.
Edinburgh, Sept. 10th.

HÆMATOGENOUS ALBUMINURIA.

To the Editors of THE LANCET.

SIRS,—I have met with three cases of albuminuria in youths of 17 to 20 years during the last few weeks. The administration of from 60 to 80 grains of calcium lactate has completely cleared this up, in one case in a few hours. The other two cases were not examined until an interval of 24 hours had elapsed. I find that a smaller dose than 60 grains is not so definite in its action. Accordingly I can vouch for the value of the work Sir A. E. Wright has performed in solving this often most perplexing problem of functional albuminuria which must have frequently completely changed, if not ruined, the prospects of many a perfectly healthy boy.

I am, Sirs, yours faithfully,
CHARLES B. PENNY.
Walbrook, E.C., Sept. 7th, 1906.

WHAT IS A SPECIALIST?

To the Editors of THE LANCET.

SIRS,—Your correspondents who are writing letters under this title do not appear to be confining themselves very strictly to supplying material for answering the question. It is not the definition of a specialist which concerns most of them; rather they are concerned to speculate how far material success is achieved by the practice of specialism, and how far the chances of such success are denied unfairly to many members of the medical profession.

Has your attention been called to a contribution by Dr. Herbert Snow in a monthly journal called the *Grand Magazine?* The paper, which I have reason to believe has disturbed the equanimity of some members of the medical profession, appears to be one of a series on "The Secret of Success," and as the seventh in succession of this series it deals with "Success in Medicine," and purports to be a feast of thought furnished by several contributors, voluntary or involuntary. The names of Sir Dyce Duckworth, Dr. Whipham, Dr. F. W. Andrewes (misspelt), Dr. Wethered, Dr. Herbert Snow, Professor Clifford Allbutt, Mr. Ernest Kingscote, M.B., Miss Aldrich Blake, M.D., Mr. Litton Forbes, Sir James Crichton Browne, and Mr. Brudenell Carter, all appear at the heads of successive paragraphs or pages, and these names are reinforced by anonymity in the shape of "An Eminent London Physician who has received a Baronetcy," and of "Sir X. Z., a well-known London specialist." In the case of several of the gentlemen mentioned it is obvious that their contributions have been involuntary, inasmuch as they consist only of extracts from their published works, but some appear to have written in reply to direct applications from the magazine. Among these, from internal evidence only, I should be inclined to place Dr. Herbert Snow, who may at least claim the merit of having escaped from conventionality. He *tells the public* that the main elements making for success in the medical profession, ranged in the order of their importance, are unscrupulousness, selfishness, hypocrisy, industry, and ability; that no one with the merest vestige of a conscience should attempt to become a medical practitioner; that everything in the nature of benevolent instincts, of kindly feeling for others, of sympathy with suffering and pain, should be sternly discouraged; and that in country districts it is advisable further to varnish your real sentiments by a cloak of religious hypocrisy. If Dr. Snow believes that these are the conditions mainly contributory to success he must believe also that the most successful members of the profession are men who have practised what he preaches. He may certainly be said to call down upon himself the condemnation generally extended to birds that foul their own nests.

The "Eminent London Physician who has received a Baronetcy" is delicious. Assuming that a person answering this description may have been asked to contribute, the application must have been thrown into the waste-paper basket and picked out by a manservant who has amused himself by giving his own version of his employer's experiences and opinions. "Jeames" is writ large over the whole of the composition. According to his story, the eminent physician is not a physician at all but a surgeon, and he became full surgeon to a "great and famous hospital" within seven years of obtaining a "minor" appointment there! He stepped into sudden notoriety by a "trivial operation" upon a well-known statesman, to whose bedside he was called in consultation. The medical "Jeames" has so far had no justice done to him in fiction, and this particular specimen ought to be induced to publish his reminiscences for the delight of mankind. Many of us could contribute an anecdote or two to such an autobiography. A friend of mine had occasion to go often to an "eminent physician," and said to Jeames, "You will be tired of opening the door to me." "Not at all, sir," was the gracious reply; "you are but a hunit in the hocean." Another Jeames was accustomed to say, during his master's occasional absences: "you had better try hopposite. There's a very respectable man hopposite as we often sends to when Sir William is habsent. His name is Jenner."

Mr. Ernest Kingscote begins by taking an absolutely irrelevant story from Sir Walter Scott and spoiling it in the telling. The hero of the original story was so far from being an Aberdeen graduate that he had not any sort of medical qualification. When Sir Walter was sheriff-depute of Selkirkshire an illiterate farrier in the district, who was charged with some minor offence, got away across the border, and a year or two afterwards Sir Walter met him accidentally in Carlisle and asked what he was doing. The man said he was practising as a doctor and told the well-known "calamy and lodomy" story with the conclusion about Flodden Field. There is no evidence that he was successful, especially as Mr. Kingscote defines "success," that is, as a "lucrative practice with congenial social surroundings." Mr. Kingscote tabulates a little catalogue of ordinary requirements in the way of "sufficient ability," "astute business instinct," &c., and provokes a quotation from Scott of quite a different character from his own:—

> "So think the vulgar. Life and Time,
> Ring all their joys in one dull chime,
> Of luxury and ease."

Part of Mr. Kingscote's advice is to avoid originality, but in quoting a precept from Assheton Smith he spells the famous sportsman's name in quite an original manner.

The passages of this extraordinary medley which appear to be editorial cuttings from books or introductory addresses are all in what lawyers, I believe, call "common form," and contain the usual recommendations to the practice of sundry prosaic virtues. But "Sir X. Z., a well-known London specialist," merits comment, as he, like your correspondents, is contributing information as to what a specialist may be. It is interesting to know that "*when* he commenced practice he passed *with distinction* all the usual examinations." Most people pass some of the usual examinations before they commence practice, and they are not informed by the examiners whether they have passed with distinction or without. In spite of his "distinction" X. Z. appears to have found himself only "one of hundreds more or less clever men," "a hunit in the hocean," in fact; and he decided to become a "specialist" because as a general physician he would have been "unable to address himself to the public." He selected a specialty "which appealed to a large class of persons, and in which a fair proportion of cases were curable," and he does not on his own showing appear to have made any endeavour to equip himself with any unusual amount of knowledge of the subjects to which his attention was professedly directed. He seems to have calculated that the recoveries of the many people who got well would be credited to his superhuman skill, and that the condition of those who did not get well would be attributed to the neglect or the want of skill of the general practitioners with whom he was associated in treating them, and of whom he was manifestly ready to make scapegoats. He is of opinion not only that specialism is the best road to success, but also that any specialty may easily be made subservient to the advancement of the man who professes it. All that is necessary is to write as much as possible in lay papers and medical periodicals, to belong to, or if necessary, start some special hospital, and, above all, to entertain as largely as possible both the rank and file of the profession and the public. It seems impossible to believe that "Sir X. Z." is a real person, but if he be a creature of the editor's imagination the medical profession has a right to resent such a picture being presented to the public as a medical portrait. "Sir X. Z.'s" self-satisfaction with his own dishonesty is amusing; it is equal to that of Gil Blas.

This autobiography of a successful specialist would seem to me to be too preposterous for credence, even in a popular lay magazine, making not the slightest appeal to intellectual people, if I did not detect in the letters of some, at least one, of your correspondents a tendency to believe that such charlatans were a force in our professional ranks. I can claim a not inconsiderable acquaintance with medical practitioners, many of them eminently successful; some, in a sense, unsuccessful, and these by no means always the least capable, but it is common experience that the ignorant and dishonest men, such as the "Sir X. Z." of the *Grand Magazine*, will almost invariably fulfil the tradition about the porcine race, that they cut their throats in swimming. It is of high advantage to be "clever," to make use of a much abused word; but it is quite possible to be "too clever by half," and in that case detection and extinction are apt to follow as cause and effect. I am, Sirs, yours faithfully,

F.R.C.S.

To the Editors of THE LANCET.

SIRS,—The interesting correspondence under this heading should have a useful issue if it not only brings to general notice the many difficulties of the present position but also enables us to see a way out. Personally, I do not think we need trouble ourselves about smoothing the path for the man whose claim to being a specialist rests on his own opinion of himself. Nor need we try to make it easy for him to secure the comfort and affluence which he imagines to be the reward of specialism. It is true that in a few instances such a man's estimate of himself may be well-founded and his failure to reap his reward may be a real loss to the community. But in the vast majority of cases such a man's claims to special capacity are as illusory as are the rewards he believes to be within his grasp if he could obtain the position he desires.

What we as a profession are more concerned with is the undoubted failure of the public to secure the advantages that it ought to secure from the particular knowledge and skill of those whose claims to specialism rests on the well-founded opinion of their fellow practitioners. From want of proper organisation of the profession a very considerable number of patients, whose simple ailments do not require it, are under treatment by men whose colleagues would unhesitatingly acclaim them as specialists, whilst still larger numbers are deprived of the services of these same specialists though their prospects of rapid recovery would certainly be increased by such help. I believe this to be due to the fundamental error as to the true basis of "specialised practice." In modern medical ethics the chief crime of a specialist is that he wanders from his speciality and treats cases not strictly within his scope. In the opinion of some it would be better if it became the chief crime of a specialist to treat any patient independently. The special knowledge of a specialist should be used not to attract members of the public to seek his aid, it should be at the disposal of other members of the profession to assist or to supplement their therapeutic efforts. I have satisfied myself that the fact that nearly all specialists, including in this term the special physician and special surgeon, as well as the eye, ear, and throat specialist, undertake independent private practice is an undoubted bar to that free use of their services which would be made by general practitioners if they restricted their work to consultations with their colleagues and to treatment carried out in coöperation with them. The introduction of a patient to Harpole-street often proves a very expensive experiment for a general practitioner. The specialist to whom the patient is sent may be scrupulous beyond reproach in his method of dealing with the case, but there are many other door-plates in the neighbourhood, and so long as specialists undertake independent treatment of cases that "come on their own," as the saying is, the danger of a patient and his friends and acquaintances acquiring a Harpole-street habit is a serious one.

There have always been a few specialists who have taken up the strictly consultative attitude and their numbers are said to be slowly increasing. If this attitude became common amongst those who are attached to the great hospitals of London it would no doubt spread to all those centres of population capable of supporting specialists. It can hardly be doubted that this would be to the advantage of the specialists themselves, of the general practitioners, and of those members of the public who have real need of the experience that can only be acquired by specialisation. It would settle once for all that the proper answer to the question, What is a specialist? is one who is so regarded by his professional colleagues. It would make it clear to the public that the profession did not regard as a specialist one who undertook to carry out treatment independently of a general practitioner. It would make it more than ever useless for a man whose colleagues did not recognise his claims as a specialist to announce that he was one on his door-plate. I am, Sirs, yours faithfully,

Sept. 10th, 1906. E.

PORTUGUESE QUARANTINE REGULATIONS.

(FROM OUR SPECIAL SANITARY COMMISSIONER.)

PART II.[1]

THE NEW *MARITIME DISINFECTING STATION AT LISBON.*—THE NEW HARBOUR WORKS.—THE BRITISH MEMBERS OF THE INTERNATIONAL MEDICAL CONGRESS AND THE "OPHIR" *BLUNDER.*—*THE OLD LAZARET FORT AND* PRISON.—THE MODERN LAZARET.

THE port of Lisbon, if considered from the point of view of the number of ships by which it is frequented, may be estimated as the twelfth in importance of all the ports of Europe. This is due in a large measure to its continual communications with the Brazils. Here, then, was established a large lazaret and its history, a somewhat sinister history, dates back for some centuries. It is situated on the left bank of the Tagus at some distance from Lisbon, nearer to the sea and nearly opposite the famous Balem tower. The importance of this lazaret may be judged from the fact that for purposes of quarantine or of disinfection of luggage in the course of ten years from 1890 to 1900 the number of persons detained here reached a total of 96,423. Now the lazaret is to a large extent abandoned and this is one among several good results which the meeting of the Fifteenth International Congress of Medicine at Lisbon helped to bring about. A maritime disinfecting station has been built at Lisbon itself and its completion was hurried forward so that everything should be in working order when the members of the Congress arrived. The station forms a part of the great scheme of the new harbour works and was opened towards the close of the year 1905. In most respects it is similar to the disinfecting station established at Leixoes and previously described. Formerly ships had to go to the lazaret on the other side of the Tagus. Here the travellers were exploited by boatmen. The water was often rough and then the boatmen would charge high prices for landing the passengers. There were many hardships and much loss of time. Now these annoyances are avoided except when quarantine detention is actually imposed and then there is no need to hurry, for there is more time than enough. This, however, only applies to infected ships. In most cases medical inspection and disinfection alone are necessary, and then, as a result of the harbour works, the ship can moor alongside of the new disinfection station. Even at low tide there are eight metres of water, so that very large ships can come alongside.

It was against this wall and close to the disinfecting station that arrangements had been made to moor the Orient Line steamer *Ophir* which was chartered to convey the greater part of the British members of the Fifteenth International Medical Congress to Lisbon. The water here is deep and pure—that is to say, there are no sewer outfalls anywhere in the neighbourhood. On the contrary, from a point near to the arsenal right away some distance on the road to the Balem tower, a main collecting sewer has been built within the new embankment. Here on this embankment an electric tram would have taken the passengers residing on the *Ophir* to the centre of the town in a few minutes, while under the embankment a main sewer conveys all sewage far away towards the sea. The appended map shows well the details I am describing (see Fig. 2) On the other side of the Commercial, or the so-called "Black Horse Square," where the *Ophir* eventually rode at anchor, are several of the worst sewer outfalls of Lisbon—indeed, the whole question of the *Ophir* is so utterly to the discredit of British management that it should not be forgotten but should be constantly recalled as a lesson and a warning for the future. It will be remembered that a scare was raised about sewer outfalls and therefore the British contingent, through their representatives, declared that they did not wish their ship to come alongside of the quay. The mooring place secured for them was consequently given up, and of course the Germans, being as usual very much better informed, eagerly availed themselves of the opportunity to secure this excellent berth for their ship the *Oceana* (see Fig. 3). Surely, before thus rashly giving up a favoured position a map of the sewers could have been procured. There was no difficulty in obtaining such a map. This map shows that where the *Ophir* should have been moored, and where Dr. Henry de Rothschild moored his yacht the *Nemesis* and the Germans their ship *Oceana*, there are no sewer outfalls whatsoever. The *Ophir*, however, and to avoid sewer outfalls where they did not exist, went to a most inconvenient position and this facing a district where they did exist—in fact, they cast anchor just opposite no less than five large sewer outfalls. Fortunately, there is so much water and the *Ophir* was so far from the shore that these five sewer-mouths were not likely to do any harm, but each time members of the British contingent went to shore in rowing boats or in a tender they had to navigate through the sewage. To land at "Black Horse Square" they had pass close to the mouth of one of the most obnoxious an odoriferous of these sewer outfalls. If in spite of th enormous volume of salt water in the Tagus those sew outfalls that still remain occasion any risk to persons o board ships then the *Ophir* anchored where the risk wa greater than if she had gone alongside as originally i tended. ("Black Horse Square" is marked in the ma just to the N. and W of the fifth s marking sewer outfal counting from the right or eastern side of the map.)

The new harbour works at Lisbon have involved a expenditure of £2,880,000, and an embankment some fiv miles long has been built together with basins, gravin docks, and vertical quays accessible to the largest ships a whatever state of the tide. There is a vertical quay 10,24 feet in length with 26 feet 3 inches of water at low tide These great works will undoubtedly have some effect upo the health of the town. Not only is a large portion of th sewage conveyed away by the main sewer laid in th embankment, but this building, by drying up the lan and preventing the exposure of mud at low tide, ha put an end to the excessive prevalence of low feve among those who lived close to the water's edge. Th mortality from typhoid fever, taking the average for periods of four years each, was equal to 0·38 per 1000 inhabitants annually from 1881 to 1885. During the next four years it was 0·35 per 1000. The new harbour works were commenced in 1892 and concluded in 1898. For the period 1891 to 1895 the maximum deaths from typhoid fever was reached, the proportion being 0·39 per 1000. Then as the works approached completion the figures fell to 0·29 per 1000 from 1898 to 1900 and to only 0·21 per 1000 from 1901 to 1905. It does not follow that the harbour works have brought about this reduction in typhoid fever, but the digging and the disturbance of the earth while the works were going on do seem to have increased the number of cases. On the other hand, the better sanitation resulting from the completion of the works was doubtless one of the contributory causes of the present falling off in the number of deaths from that disease

The new maritime disinfecting station has been built on a portion of the vertical quay to the west of Lisbon, and at the base of the hill where the Royal palace of Necessidados is situated. The railway lines are laid here so that goods can be loaded on the trucks as soon as they have been disinfected. From the disinf[illegible]tation luggage can be sent direct to any part of E from a ship to take it to a railway station in Lisbon. Soon a railway station will be built here and then passengers will be able to take their tickets and depart without penetrating the city. At present, however, only the line exists and not the railway station. But there is a post and telegraph office, so that the passengers can at once communicate with their friends, and there are stationery and desks ready for them in the waiting-rooms.

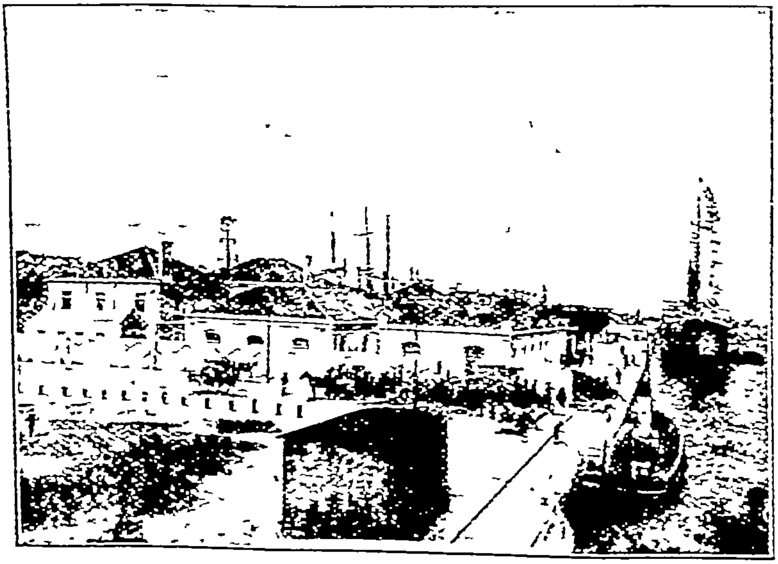
FIG 3



The new maritime disinfecting station at Lisbon In the distance, with display of flags, the s.s. Oceana moored alongside of the new sea wall, and having on board the German contingent of the Fifteenth International Congress of Medicine.

The first class waiting-room has a parquetted floor and all necessary comforts. The medical officers and the secretaries have commodious surgeries and offices and, as at Oporto, there are the baths with rooms on one side in which to undress and rooms on the other side where the disinfected clothing is put on. The same is provided for the attendants, the dock labourers, and all who have to handle the clothes or merchandise that may be infected. Throughout, here as at Leixoes, there are excellent English closets, with a two-gallon flush, which drain into Mouras tanks, the overflow going to the harbour. Leather or hides and other articles that are more likely to carry germs are in preference disinfected at the lazaret on the other side of the Tagus. At Lisbon the Clayton apparatus, and it is of the largest model, stands on shore. As the ships come alongside it is easy by tubes to put it in connexion with the hold or cabins which have to be disinfected. On shore there are six large rooms where goods may be spread out; perforated pipes go all round these places and discharge sulphurous fumes. There are also apertures in the wall where ordinary sulphur can be ignited. Then there are some small rooms which are used when there is not much to fumigate. Three

Geneste and Herscher stoves for disinfecting with steam under pressure are generally used for clothes, underclothes, and bedding, *and these are of the most recent* pattern. The wall and flooring are so arranged as to be easily washed. The fittings are mostly of metal so that the *premises can be kept in a clean aseptic condition.* Finally, there are some small barracks for soldiers and custom-house officials which are admirably clean and well drained. *The building throughout* is illuminated with electricity and there is nothing gloomy, forbidding, or unpleasant about the place.

Very different, indeed, is the impression that will be produced upon anyone who visits the old lazaret on the other side of the water. The experience is all the more interesting as different stages through which the practice of quarantine has passed may be seen in a manner that constitutes a genuine object-lesson. The approach from the water is most picturesque. Just where the broad Tagus narrows as it nears the sea the Moors, to defend the entrance of the Lisbon waters, constructed on the northern side a fortress where to-day the majestic Belem Tower stands. On the southern side, *just opposite this tower,* the Portuguese built the fortress of St. Sebastian Caparica which constituted a part of the military defence of Lisbon up to 1815, when it was converted into the sanitary defence of the capital. Before that date the quarantine station was in the little village of Trafaria which is in the immediate neighbourhood but nearer the mouth of the river. *In the casemates of* the fort unfortunate travellers were kept in quarantine. As these places are so built as to protect soldiers from shot or shell they have but small *entrances and little light or ventilation.* Nor were any artificial means employed to pump air to the farther end of these narrow casemates which look like dungeons and have no windows. *To be imprisoned in such* places was certainly enough to favour the development of many diseases.

Approaching the lazaret in the *steam* launch of the port sanitary authority *this fort is* seen poised on the edge of a precipitous yellow sandstone rock. Lower down, as well as *on ledges towards the summit of the cliff, there is some* luxuriant vegetation *in which eucalyptus* trees *predominate.* At the foot of the hill and cliff there are a great number of low buildings and *sheds. Here merchandise was disinfected.* But *only small boats and barges can approach* the little landing-stage. It must have been a great trouble and expense to unload in barges or tenders the cargo of a *ship at anchor* and *the luggage of passengers, to bring it* all to shore, and then to take it back again to the ship after dis*infection.* The passengers *had to walk up the hill between* walls 30 to 40 feet high that block out all view of the surrounding country. Nor is it possible to see more than a few yards in front or behind *for the passage between the walls* twists and twirls. At each corner or turn there is a sentinel box. This was deemed necessary to guard the approach to the fortress. *But when finally one of the terraces of the* fort is reached then a sublime view of the Tagus is obtained, disclosing fleets at anchor in the blue waters and beyond the white glare of the *houses and* palaces of Lisbon. How tantalising such a view must have been to the quarantine prisoners. But the old casemates of this fortress are *only* shown as curiosities, as historical mementoes of the harsh measures formerly applied. A small portion of the fort, which is more *like* an *ordinary* house and *was probably originally* intended for the *officers'* quarters, is still used, but only on rare occasions, for purposes of isolation. Here I was shown the two sombre *rooms where, in 1899, the medical officer* in charge lived in strict isolation during 21 days with a soldier who came from Oporto and was found to be suffering from plague. *Here also* a professor who contracted the plague was confined. It was not thought that such rigorous isolation was necessary; but a great panic *prevailed* at that moment, and it was more for the sake of quieting the people at Lisbon than because there was any real danger that these exaggerated precautions were taken.

The lazaret that is now in use stands behind the picturesque and threatening fortress. Though the construction was commenced *as* far back as 1860, and though the building was inaugurated in 1865, it is still considered a model institution. While the fort is on the *crest of the precipitous* rock or *cliff the* lazaret is at a higher level on the top of the hill which caps the rock. In design it may be compared to a wheel which has seven spokes, *each consisting* of long *buildings of three or four* storeys high, of which six are furnished for the reception of travellers and the seventh for the *staff. The whole construction is like* a succession of oblong or pavilion-shaped hotels all pointing to the one and same centre but separated from each other. A circular *central structure that* may be called the hub of the wheel plays a very important part in the scheme. Here on the ground floor are the kitchen, sculleries, and all that *relates to the feeding of the community.* But the spokes of the wheel instead of penetrating the hub are separated from it by a space or circular court six metres wide. *The first floor above the kitchen is a large circular hall* surrounded by windows which face the windows at the extremities of seven long pavilions. Here visitors are admitted *and across the open space of the circular court* they may speak to the persons in quarantine. Thus from the hub of the wheel the visitor shouts to the inhabitants *of the spokes of the* wheel whatever he may have to say. It is an ingenious method of keeping people apart and yet of enabling them to see and speak to each other. The windows *are protected by strong wire grating, so that nothing should* be thrown across. On one occasion there were 1500 persons simultaneously in quarantine in these buildings and a greater *number could have been accommodated. But now* as quarantine is so rarely enforced the place has a very deserted aspect. Nevertheless, in one *dining-room the table* was all ready *laid for* some 30 or 40 people and there were *cooks* in the kitchen ready to prepare dinner for them. At any moment an *infected ship might come into port* and *its crew and passengers have to be detained. The third-class* passengers sleep in *long* dormitories under the roof on the top floor. It seemed *to me* that if all the beds were occupied *there would be overcrowding. The first-class passengers* have drawing-rooms and terraces commanding panoramic views and it cannot be said that there *is any* hardship in *being detained for a few days on so beautiful a spot.* It is *not like the old,* dark, long, narrow casemates with their plank beds at the foot of each wall. No great hardship is *now involved in being detained, still the question may be* asked whether detention of healthy passengers *might not* be abandoned altogether. From 1880 to 1901 196,457 *passengers and crews have been detained* at the Lisbon lazaret. What illness of a dangerous character occurred among all these people after they had landed? Five cases of *yellow fever are recorded; the last happened in 1902.* And all the five patients were members of ships' crews and not passengers, and were probably ill before they landed. In *the same way there was one sailor* who had cholera in 1893. *The few cases of plague* observed seemed to indicate that the disease had been contracted on board and *not at the infected ports,* and this not by passengers but by handling cargo. So now much attention is devoted to the disinfection of merchandise, *of luggage, of personal linen,* and the killing *of rats and other vermin, which is probably much* more useful than detaining passengers in quarantine. Thus is Portugal coming into line with the most *advanced countries so far as the question of quarantine is concerned.*

MANCHESTER.

(FROM OUR OWN *CORRESPONDENT.*)

Colony for Epileptics at Langho.

As was mentioned last week, a new colony for epileptics was opened at Langho on *Sept. 3rd by the* Earl of Derby, Lord Lieutenant of Lancashire. It is the outcome of a joint scheme promoted by the guardians of the *Chorlton union and those of the* township of Manchester. There have, of course, been privately supported institutions of a similar character but *this is the first public epileptic home in the country.* It is in an open situation near Whalley in the valley of the Ribble. The present buildings will accommodate 272 patients *with the necessary staff,* but there is room for large extensions as they may be required. There are separate "homes" for the patients, *each containing* 40 beds, and they are designed *to* have, as far as possible, "a cheerful domestic character." Although a family of 40 requires a considerable *enlargement of our notions of the* domestic hearth, the change will be a happy one for the inmates, who have so far *had to be accommodated* in the necessarily somewhat unsympathetic refuge of the workhouses. The unsatisfactory results to themselves and the other inmates have *led the guardians to attempt* to deal with the *difficult* problem of the epileptics on a humane and, it is believed, scientific basis. It is a step in the direction of more careful classification of workhouse patients. The estate at Langho comprises 166 acres of elevated and undulating land, with extensive views of the surrounding country. There are 16 buildings now erected. The administrative block is in a central position, while there are a receiving and hospital block, an assembly hall, a central kitchen and store block, medical superintendent's house, a power house, general laundry block, with workshops for brushmakers, upholsterers, carpenters, tailors, shoemakers, and plumbers. The homes are in groups to the right and left of the administrative buildings, and are fitted up on the most approved principles. The cost, with administrative capacity for about 500 patients, is £78,500, which, with the cost of the site, brings it to about £100,000. The lighting is by electricity generated in the power house and water is obtained from the Blackburn main. After the opening ceremony a luncheon took place, presided over by Dr. J. M. Rhodes. In proposing the health of Lord Derby, he spoke of the unhappy lot of epileptics, whether in or outside our workhouses. Employments were almost, and where machinery was used, quite closed to them. Since 1890 the rate of epilepsy had been declining, and "he was not sure that the enormous number of people in the asylums had not prevented the multiplication of the unfit. He hoped it was so. Many epileptics could do good hard work, and the best kind for them—work on the land—would be provided at that colony."

Black Smoke in Bury.

People who live in a smoky town get so accustomed to it that they are nearly unconscious of the serious evils that accompany the pouring out of unconsumed carbon with its tarry associates. The Bury town council passed a resolution recently to restrict the emission of black smoke to seven minutes during the hour instead of allowing ten minutes as at present. At a meeting on Sept. 6th some of the members thought the time allowed too short and that they should have eight minutes' grace. One of the medical members, Dr. Greenhalgh, said that he could not understand this tender consideration in regard to the question of black smoke. Personally, he thought that it should be abolished and it might easily be reduced to a minimum. No doubt he is right, and it seems discreditable that such a nuisance as black smoke should, in these days of advanced science, be allowed to pollute and defile so much of the manufacturing districts. Even Manchester, not reputed a smokeless town, only allows three minutes to the hour, but it is only fair to give credit to Salford, which apparently loves smoke more than her neighbour, and therefore gives a more liberal allowance of time for the emission of black fumes which roll over Manchester regardless of the dark boundary, the Irwell.

Antivaccinationists' Refuge.

To show how well Heywood deserves the title sometimes given to it of the antivaccinationists' refuge it is only necessary to mention the proceedings of one day about a fortnight since. A man came from Audley, Staffordshire, and said that he came purposely to get "the certificate," which was granted. Certificates were also granted to 15 other applicants from Bury, Summerseat, Newton Heath, Levenshulme, Radcliffe, and Pendleton.

(FROM OUR OWN CORRESPONDENTS.)

The Etiology of Plague.

THE opening lecture of the post-graduate course in connexion with the Glasgow Royal Infirmary was delivered on the afternoon of Sept. 4th by Major George Lamb, I.M.S., director of the Pasteur Institute of India and chief of the Royal Commission on Plague. The lecture, which was largely attended, dealt with the Etiology of Plague. Major Lamb first drew attention to the main conclusions which are generally accepted in connexion with the epidemiology of plague. These, he said, are: (1) Plague, except in the pneumonic form, is not particularly infectious or contagious, and man-to-man infection plays no important part in the spread of the disease in India; (2) the infection of plague is in the houses and huts and may remain there for some time; (3) plague, when once started, exhibits a most marked seasonal prevalence; (4) epidemic plague is associated with, and generally preceded by, an epizootic amongst rats. The lecturer next went on to discuss the possible means of the spread of plague from rat to rat and from rat to man. He showed from experimental and statistical evidence that alimentary infection does not take place. Further, he showed that all the facts pointed to the infection of plague finding an entrance to the body through the cutaneous surface. In discussing the methods by means of which cutaneous infection might take place it was definitely showed that infection from the soil through cracks or abrasions of the skin of the foot could play no part in the spread of the disease. Major Lamb then described in considerable detail the series of investigations and ingenious experiments he had carried out, as a result of which it seemed impossible to escape the conviction that the rat flea was the means by which infection is carried from rat to rat and from man to man. The work which the commission still has to face is to find how the flea transmits the infection, and also to discover an explanation for the seasonal prevalence of the plague. Major Lamb, in conclusion, stated that the rat which occurs in Britain is the brown Norwegian rat and not the black rat of India, and it is probably on that account that there has been no serious outbreak of plague in this country. The particular flea which carries the infection has been found only once in this country.

The West of Scotland Convalescent Home, Dunoon.

The thirty-seventh annual report of this institution has just been issued by the directors. Up to the present time since the opening of the home 110,357 patients have been admitted. At present there is accommodation for 250 convalescents, and during the past year 4756 new cases were received. Of these 4433 were perfectly restored to health, 188 were much improved, 132 did not improve, three died, and 248 are still in the institution. The greater number of the patients were drawn from the city of Glasgow, but a considerable proportion came from villages and towns many miles distant. Financially, the year has been a most successful one. The total income from all sources has been £9310 12*s*. 7*d*., while the expenditure (including a transference of £2000 from ordinary bank account to the fund available for building purposes) has been £8762 2*s*. 2*d*. This leaves a balance of £548 10*s*. 5*d*. on the right side. Owing to the great demand for admission the directors have decided again to add to their extensive buildings. The new wing will provide 57 additional beds, as well as increased facilities for the working of the institution. This will cost nearly £6000 and will be the sixth addition to the buildings since their inauguration in 1869. It is pointed out in the report that although in summer there are more applicants for admission than can be accommodated yet in winter this is by no means the case.

Sept. 11th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Dublin Sanitary Association.

THE council of the Dublin Sanitary Association met at its offices in Dame-street on Sept. 7th and directed attention to the number of private slaughter-houses still existent in the city. The corporation is now provided with an admirable public abattoir, but comparatively little use is made of it, for there are at present 61 private slaughter-houses in which, according to a recent weekly return, 2872 animals were killed, while less than 700 were dealt with at the corporation establishment.

Sequel to the Longford County Infirmary Inquiry.

Another meeting of the committee of management of the Longford Infirmary was held on Sept. 5th, Dr. Hoare, the Roman Catholic Bishop, presiding. With reference to Mr. Mayne's report to the Local Government Board as to the insanitary state of the infirmary and to the necessity that the wards should be properly disinfected, Mr. J. W. Bond proposed a motion:—

> That some competent person be asked to make a report as to the work necessary for the disinfection and cleansing of the infirmary, with information also as to the probable cost.

The chairman proposed as an amendment:—

> That the workhouse hospital may be utilised until a solution of the present difficulty is found.

This amendment was lost and by consent the county surveyor was accepted as the person who should report on the repairs necessary to the infirmary, and Mr. Bond's motion was carried.

Medical Officer of Health of Belfast.

At a meeting of the corporation of Belfast in committee, held on Sept 5th, the question of the salary to be paid to the new medical officer of health was considered. The council had previously fixed £600 a year but the Local Government Board objected that this was too small for a city of the size and importance of Belfast and requested the council to reconsider the manner. Hence the meeting of Sept. 5th. The chairman of the public health committee moved :—

> That it be a recommendation to the council to rescind the resolution passed on July 2nd fixing the salary of the medical superintendent officer of health at £600 and to fix the salary of that office at £800 per annum.

An amendment reaffirming the salary of £600 fixed by the council was moved and on a vote it was carried by 26 to 11 votes. As a result we have a salary of £600 a year offered for a medical officer of health in a city of 348,965 inhabitants Nor is this all. The medical officer of health of Belfast will have to provide the solution of almost every public-health question that has been settled in other cities, such as the main drainage of the city, the defective housing, the control of the milk-supply, infantile mortality, and prevalence of tuberculosis. Imagine a city the largest in population in Ireland paying (for example) its coroner, who is allowed private practice, more than its medical officer of health who must devote all his time to the duties. Interest now turns on what the Local Government Board will do; it will not be surprising if it refused to sanction the benighted action of the Belfast corporation.

The Recent Heat Wave.

Nothing could be more satisfactory than the ventilation of the new Royal Victoria Hospital during the recent warm weather. The highest shade temperature recorded outside the hospital in Belfast was 85° F. and on that day the inside temperature of the Royal Victoria Hospital was 67°. Thanks to the admirable working of the plenum system another pleasing feature was the total absence of flies.

Rainfall in August.

During August, in the vicinity of Belfast, rain fell on 22 days to the extent of 5·47 inches; that is almost one inch beyond the average for that month. The total rainfall for the past year is 26 99 inches, which is more than one inch beyond the average.

Sept. 11th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The Treatment of Acute Inflammatory Affections of the Intestine by Warm Baths.

AT a meeting of the French Association for the Advancement of Sciences held at Lyons from August 2nd to 7th Dr. Pujo reminded the meeting that the treatment of acute affections of the intestine has now for many years resolved itself almost exclusively into the use of ice and opium or else operation. Dr. Pujo recommended the warm bath of which the temperature should vary according to the season. The baths should be given frequently during a period of two hours followed by a similar period in bed. These alternations should be continued until the point of concentration of the disease has been dispersed, a result which obtains in a few days. Dr. Pujo has met with invariable success, and out of over 60 cases, 20 at least showed marked signs of true appendicitis and some of them of suppurative appendicitis. In this latter case quinine was given as well as the baths, and he also found it useful occasionally to give opium and calomel in addition Naturally this method of treatment demands the most careful precautions as to placing the patient in the bath. No sudden movement should be allowed and the patient should be kept straightened out as far as possible, only not so straight as to bring about compression of the lower part of the abdomen.

The Hæmopoietic Property of Serum.

At the same meeting M. P. Carnot and Mlle. Deflandre communicated the result of some researches which they had undertaken as to the cause of the renovation of the blood in bleeding. The result of these researches had been to confirm the presence in the serum of animals which had been bled of a substance capable of stimulating hæmopoiesis, and this substance they propose to call hæmopoietin as opposed to hæmolysin. Their experiments were carried out on the rabbit, and they found that if a rabbit was copiously bled, and that on the following day serum was taken from one of these animals then in the full tide of making fresh blood, and if this serum were injected into another rabbit, the latter on the following day showed marked hyperglobuly. As a rule, the red corpuscles showed 3 000,000 per cubic millimetre but a much higher rate was obtained in some cases. In one, for instance, on the third day the figure was 6 000,000 Compared with the hæmopoietic activity of the blood or serum collected during the full tide of blood renovation that of normal blood or serum is very weak. If the same animal is too frequently bled the hæmopoietic activity of the serum diminishes and finally it is replaced by hæmolytic activity It is probable that in the normal state these two factors counterbalance one another and that under the influence of certain factors sometimes one and sometimes the other predominates. M. Carnot and Mlle. Deflandre added that the hæmopoietic substance is not found in the figured elements of the blood but in the serum. It is destroyed at a temperature of 56° C and is most abundant in the blood on the morrow of a bleeding. Administration of it by subcutaneous injection is just as efficacious as when given intravenously. They consider that this treatment may be of great therapeutical use in certain cases of anæmia, and, in fact, in a case treated in this way they observed an augmentation of the red blood corpuscles running up to 1,000,000 in 48 hours.

The Fight against Lead Poisoning.

Professor Armand Gautier has just submitted to the Council of Hygiene and Public Health of the Seine a report upon cases of lead poisoning observed in the course of the last three years. The number of cases of lead poisoning in 1903 doubled in 1904 and for 1905 it doubled again. Professor Gautier concludes that white lead should be absolutely forbidden for painting the insides of buildings, but as far as regards the outside of buildings he expresses himself willing to wait until the Expert Commission nominated by the Minister of Commerce has sent in its report.

Sept. 11th.

VIENNA.

(FROM OUR OWN CORRESPONDENT.)

Restrictions on Experimental Treatment in Hospitals.

AT a recent meeting of the Medical Union of Vienna there was an animated discussion on an ordinance which has just been issued by the Minister of the Interior regarding the use of new methods of treatment in the case of hospital patients. This ordinance directs that experiments with new remedies or new methods are not to be made unless the patient has been previously informed of the fact and has given his consent. A full record must be kept showing all the details of the experiment as well as the names of the experimenters, assistants, and patients. The director of the clinic or the ward must either be present or must in some way supervise the whole proceedings, and a full report must be sent to the hospital director. Novel surgical operations must have been tried on animals before being employed for patients. Such methods may, however, be used in cases of emergency if previous methods of operating are dangerous or are likely to be unsuccessful The Austrian law is somewhat strict in defining the liability of a medical practitioner towards his patient; the penalties for neglect are regulated by paragraph 1325, which may be quoted here as the new regulation expressly calls attention to its existence. It is to the effect that anyone who inflicts bodily injury on another person must pay all the expenses of the medical attendance and medicine, as well as any other outlay incurred by the injured person in consequence of the injury. The injured person may claim compensation for the pain sustained through such act and also compensation for loss of income, or he may claim, if he becomes permanently unfit for work, a sum equivalent to the loss of his future income. Paragraph 1327 makes the person who inflicts the injury responsible to the family of the injured person if the latter dies through such an act, by awarding them a certain sum as compensation. A medical man may also become responsible to a patient under the Civil Code, paragraph 355, the so-called paragraph *contra leges artis*, which stipulates that if a medical man shows gross professional ignorance in treating patients, and if such ignorance results in harm to the patient his diploma may be cancelled and he may be struck off the list of men entitled to practise medicine until he proves by passing an examination that he has a sufficient knowledge of his profession. If death results from such neglect imprisonment for a period varying from one month to one year may be inflicted upon him in addition to the financial responsibility. The law therefore is careful to protect the patient against the practitioner, but, on the other hand, the practitioner has hardly any protection against his patients. It is to be expected that the recent ordinance will not interfere materially with the scientific work going on in the clinics. It is in reality a concession to an influential section of the population, consisting of persons favourably inclined to the antivivisectionist movement. It will, however, serve as a valuable check upon some indefensible experiments which are made now and then.

Reform of the Out-patient Department in the State Hospitals.

The governor of Lower Austria, as chief of the board of the State hospitals, is now introducing a long-desired reform. The main feature of the new system is the prevention of abuse of the hospitals by the wealthier classes and for this purpose an Armutszeugnis, or documentary evidence of inability to pay medical fees, must be shown by the applicant. Such evidence is obtainable from the landlord of the house where the applicant lives or from the guardians of the poor in each district and must prove that the applicant's rent is less than 600 kronen (£25) and that his income does not exceed £100 a year. On presentation of this document the applicant receives at the hospital a card admitting him to the out-patient department. Persons in easy circumstances will in this way be prevented from attending the hospitals and those who are in the service of shopkeepers, manufacturers, and similar employers of labour will have to be attended by practitioners engaged in accordance with the Employers' Medical Provision Act of 1889, under which all persons occupying posts in business houses are entitled to medical attendance. (This Act itself is an old source of grievance amongst the bulk of the practitioners.) Domestic servants, also, who form a large proportion of the out-patients, will in future be debarred and will have to look to their employers to obtain medical attendance for them. Exceptions are granted if the treatment requires special apparatus, special knowledge, or a very long time, and also in cases of emergency, but in such circumstances moderate payments may be claimed from well-to-do persons. Discharged in-patients may continue as out-patients until their recovery. Bandages will be given for use in the hospitals but not for use at home, and no medicine will be supplied except to patients unable to pay for it. Infectious cases will be referred to the isolation hospitals and the police must be informed if in any instance violence or foul play is suspected. Otherwise no writing except the making of short notes will be required from the medical staff. Private patients may be sent to the out-patient department by any medical practitioner or professor if the case is interesting; for such patients a special admission card is necessary and treatment is free. It is estimated that the saving which will result from these new regulations will amount to not less than 24 per cent. of the yearly expenditure, but the number of the patients will, of course, be greatly reduced, so that the effect on scientific work and the opportunities for clinical teaching must be watched.

The Sale of Flowers and Fruit.

The sale of flowers and fruit is largely carried on by street-vendors, who do not always comply with the rules of hygiene necessary in this line of business. As an outcome of some convictions for offences against the regulations relative to food supply the board of health now requires the dealers in such articles to keep their fruit covered, so as to protect it from dust and other contamination, and not to offer for sale anything which is in a damaged or bad condition. Offenders will be liable to have their stock seized and their licences cancelled.

Injury to the Conus Medullaris.

At a recent meeting of the Society for the Study of Psychiatry and Neurology Professor Schlesinger showed a man who 16 years ago fell from the third floor of a house and was paralysed up to the umbilicus. After three years his condition improved so much that he was able to resume work, when he again fell from a considerable height. He suffered again from paralysis of the lower extremities, with disturbances of the function of the bladder and rectum. This time only the limbs recovered, and the impaired action of the bladder remained so that a severe septic cystitis endangered the life of the patient. He suffers at the present time—seven years after the second fall—from weakness of the legs, loss of sensation for heat and cold in the region supplied by the sacral and first lumbar segments, and incontinence of urine which trickles away without the patient feeling it. Sexual desire is entirely absent, but the man has become the father of two children. In similar cases in which necropsies have been made it has been found that the entire sacral medulla and the grey substance of the lumbar portion of the spinal cord were destroyed. Patients may live for many years with these lesions and may have children, so that the prognosis is not unfavourable, but there is always a liability to ascending pyelonephritis consequent upon the inevitable cystitis.

Sept. 11th.

Obituary.

JOHN CAMERON, M.D. GLASG., F.R.C.P. LOND.

THE death of Dr. John Cameron, which took place at his residence, 4, Rodney-street, Liverpool, on August 20th, at the age of 88 years, has removed a prominent figure from the ranks of the profession in that town. Dr. Cameron went to Liverpool from the Highlands of Scotland in 1839, in which year he obtained the diploma of the Royal College of Surgeons of Edinburgh. For a few years he was identified with the Liverpool South Dispensary as one of its medical officers. In 1843 he graduated as M.D. at the University of Glasgow and in 1873 he became a Fellow of the Royal College of Physicians of London, having obtained the Membership in 1859. A feature in Dr. Cameron's life was his long association with the Royal Southern Hospital. He was originally appointed physician to the hospital for ten years, the customary period at the time. At the end of the term he was appointed for a further period of ten years and later the appointment was made lifelong, his resignation only taking place a few years back. He was always ready to assist the cause of medical science and when the University College scheme was first started he contributed £500. His connexion with the Liverpool Medical Institution was of a unique character. On March 15th, 1899, a gathering was held in the large theatre of the society to celebrate the diamond jubilee of his membership. Having joined the society in 1839 he had been a member of council for many years; he was twice general secretary, vice-president in 1868, and president during the session 1872–73. For 50 years he was continuously in office as a trustee and no member attended more assiduously to his duties. The diamond jubilee gathering was an interesting occasion and was largely attended by the members. The funeral took place on August 23rd and was quite a representative one.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following foreign eminent medical men are announced:—Dr. O. Vierordt, professor of medicine in Heidelberg.—Dr. Jaumes, formerly professor of forensic medicine in Montpellier.—Dr. Gouraud, formerly on the staff of the Paris Hospitals.—Dr. Morache, professor of forensic medicine in the University of Bordeaux.—Dr. Isidor von Neumann, emeritus professor of dermatology and syphilis in Vienna, at the age of 74 years. He studied in Vienna and was assistant to Hebra and subsequently succeeded to his chair. His published works include a Manual of Skin Diseases and another on Syphilis. Three years ago he was ennobled by the Emperor.

Medical News.

THE DUTIES OF PUBLIC VACCINATORS.—At a meeting of the St. Columb (Cornwall) board of guardians held on August 30th a letter was read from the Local Government Board in reference to one of the public vaccinators of the union. The Board stated that the gentleman referred to was in the habit of granting certificates of postponement on trivial grounds, that he had failed to vaccinate his own child successfully, and that he had given a certificate of insusceptibility for the infant. The Board further wished to know if the guardians had investigated the matter and also wished to know the three dates on which the public vaccinator operated on his own child, the source from which he obtained the lymph, and the results which the public vaccinator had obtained whilst using similar lymph on other children. After some discussion the guardians decided to ask the public vaccinator for a reply to these allegations.

THE LOCAL AUTHORITIES (TREASURY POWERS) ACT, 1906.—The Local Government Board has issued circulars to burial boards, town councils, urban district councils, and metropolitan borough councils drawing the attention of these bodies to certain of the provisions contained in the above-mentioned Act. The Act was passed for the purpose of transferring to the Local Government Board certain powers hitherto vested in the Treasury under enactments relating to local authorities. For instance, the borrowing of moneys by burial boards for the purposes of the Burial Acts had to be approved by the Treasury and in the same way the appropriation or alienation of land for the purposes of the Baths and Washhouses Acts had to be approved by the Treasury. Under the new Act the Local Government Board is substituted for the Treasury and it provides that the Board shall exercise as regards every local authority in England and Wales, except the London County Council, any power conferred on the Treasury by any enactment contained in, applied by, or incorporated with the Baths and Washhouses Acts, 1846 to 1899, or the Burial Acts, 1852 to 1900, or any local or private Act as respects dealings with property, loans, and matters connected therewith, and that all such enactments, and all enactments referring to the powers so conferred, shall be construed accordingly. Baths and washhouses, and the questions arising in regard to the disposal of the dead indubitably affect public health, and as the Local Government Board is more in touch with local authorities than that *quasi* obstruction the Treasury, it is likely that the new Act may have a useful bearing upon public health.

LITERARY INTELLIGENCE.—We have received a preliminary prospectus of a journal to be called the *International Medical Review*, to be edited by Dr Hugo Neumann of Berlin. The prospectus states that the object of the review in question is to establish under the form of a periodical journal a permanent exchange of professional knowledge and experience among the medical faculty of the whole civilised world. It is intended to publish the review quarterly and each issue will appear simultaneously in six languages—viz., English, German, French, Italian, Portuguese, and Spanish. The copies will be distributed among medical men in that language which or either native to the country in which they live is is the most generally understood there of all foreign languages. Thus, the review will be distributed in English to medical practitioners in Great Britain, her various colonies and dependencies, in the United States of America, and of foreign countries, in Japan and Persia. The German edition will be distributed to medical practitioners in German-speaking countries of Europe and also in Denmark, Holland, Norway and Sweden, the Russian Baltic provinces, and Finland. The French edition will be distributed to medical practitioners in France and her colonies, and in Belgium Bulgaria, the Dutch East and West Indies, and Greece. The Spanish edition will be distributed in Spain, the Spanish-speaking countries of South America, and the West Indian islands. The review will not only treat of purely scientific medicine but also of such medico-sociological subjects as the treatment of tuberculosis, the question of prostitution, the questions dealing with the medical laws and regulations in the various countries, climatic conditions, epidemiology, and tropical therapeutics. A special section is to be set aside for questions and answers. An epitome from the various medical publications will be given, especially drawn up with a view to meeting the wants of general practitioners. We await the appearance of the first number of this international review with interest.—A book entitled "Hypnotism and Suggestion" by Dr. Edwin Ash will shortly be published by Mr. J. Jacobs, 149, Edgware-road, London, W. The work, it is stated, is devoted almost entirely to practical hypnotism. It will consist of about 155 pages and the price will be 4*s.* net.—Messrs. Baillière, Tindall, and Cox have recently published a fifth edition, rewritten and revised throughout, of Professor Stewart's "Physiology." The fourth edition referred to in our issue of Sept. 1st is out of print.

ENTERIC FEVER IN PONTYPOOL.—Enteric fever has broken out in Pontypool and the surrounding district and up to Sept. 8th about 90 cases had been notified. At a meeting of the Pontypool district council held on Sept. 5th the medical officer of health (Mr. S. Butler Mason) reported that the epidemic was increasing, notwithstanding that the supply of water which had been regarded with suspicion had been cut off.

OPHTHALMIC APPOINTMENTS IN EGYPT.—The following appointments to sub-inspectorships have been recently made in connexion with the ophthalmic hospitals in Egypt:—Mr. George H. McLaren, M.R.C.S. Eng., L.R.C.P. Lond., late house surgeon, Birmingham and Midland Eye Hospital; and Mr. I. G. Macdonald, M.R.C.S. Eng., L.R.C.P. Lond., late house surgeon, Royal Westminster Ophthalmic Hospital. The appointments are for two years at a salary of £510 a year, with certain allowances. Mr. McLaren has already taken up his duties in Egypt and Mr. Macdonald will join the service in Egypt at the end of October.

CENTENARIANS.—Mr. John Burke of Tremadoc, who is 103 years of age, was quite recently a witness in a right-of-way case at the Festiniog county court. He declared that he had used the path nearly 100 years ago.—The *Times* of Sept. 8th states that Mr. Thomas Price of Welton, near Daventry, has attained his 103rd year. He is in possession of his faculties, and he recalls memorable events occurring in his early manhood, including the birth of Queen Victoria. He drove a well-known county family to London in their coach to attend her late Majesty's coronation. Mrs. Finn, one of his daughters, living at Strand-on-the-Green, Chiswick, is 77 years of age, and has several great-grandchildren.—Mrs. Mary Glover of Hoops on Sept. 7th attained the hundredth anniversary of her birthday.

ROCHDALE INFIRMARY.—A welcome donation of £5000 has been given by the trustees of the late Mr. James Holden, who left nearly a quarter of a million for charitable purposes, to the special fund which is being raised to extend the Rochdale Infirmary as a permanent memorial of the town's jubilee of incorporation. This is in addition to other large sums given by the trustees to the infirmary, and brings up the extension fund to nearly £20,000. As regards the jubilee itself, the chief interest, medically, lies in a comparison of the sanitary condition of the town at the present day, and at the time of incorporation. The population has grown from about 33 000 to 86 390, the increase being partly due to two extensions of territory. About 1856 the birth-rate averaged 34·5 per 1000, and has gradually fallen, almost year by year, to its present low rate of 23·2. In the old borough the death-rate was 23·4, and it gradually increased till it reached 27·0 per 1000. With the increased area given by the extension in 1872 the rate began to fall till it is now 16·7. During the 50 years the reduction in the death-rate has been 6·7 per 1000, compared with 6·0 for England and Wales. These figures are taken from an interesting chapter supplied by Dr. J. Henry, the medical officer of health, to the volume giving the history of Rochdale and marking its jubilee. Dr. Henry attributes the improvement to better sanitary provisions, greater knowledge of true cleanliness, the extension of the borough and diminished density of population, the many Factory and Workshop Acts dealing with steam, temperature, ventilation, &c., and the adoption of improved closet systems. Many years ago the town was distinguished by the very general adoption of dry closets.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to The Lancet *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.*

Atkinson, E. L., M.R.C.S., L.R.C.P., has been appointed Senior Obstetric House Physician at St. Thomas's Hospital.

Cann, F. J. H., M.B. Lond., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Dawlish District of the county of Devon.

Clarkson, F., M.B., B.S. Durh., has been appointed a Resident Assistant in the Ear Department at St. Thomas's Hospital.

Corner, S. G., M.B., Ch.B. Edin., has been appointed House Surgeon at the Essex and Colchester Hospital.

Derry, Bartholomew Gidley, L.R.C.P. Lond., M.R.C.S. Eng., has been re-appointed Medical Officer of Health for Bodmin (Cornwall).

Dodgson, George Stanley, M.B., B.C. Camb., has been appointed Medical Officer to the Sherburn Hospital, near Durham.

Eckenstein, K. E., M.R.C.S., L.R.C.P., has been appointed a Resident Assistant in the Children's Surgical Department at St. Thomas's Hospital.

Eyre, C. R. B., M.R.C.S., L.R.C.P., has been appointed Junior Obstetric House Physician at St. Thomas's Hospital.

Flitcroft, Thomas E., L.R.C.P. & S. Edin., L.F.P.S. Glasg., has been appointed Resident Medical Officer at the Warrington Union Infirmary.

Gotelee, H. E., M.R.C.S., L.R.C.P., has been appointed Senior Ophthalmic House Surgeon at St. Thomas's Hospital.

Gray, H. T., B.C. Cantab., M.R.C.S., L.R.C.P., has been appointed a Resident Assistant in the Throat Department at St. Thomas's Hospital.

Jeffrey, G. Rutherford, M.B., Ch.B., has been appointed Senior Assistant Physician to the Crichton Royal Institution, Dumfries.

Maclean, I. C., M.R.C.S., L.R.C.P., has been appointed a Resident Assistant in the Children's Surgical Department and also in the X Ray Department at St. Thomas's Hospital.

Roberts, R. J., L.R.C.P. & S. Edin., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Corris District of the counties of Merioneth and Montgomery.

Thomas, A. H., L.S.A., has been appointed Certifying Surgeon under the Factory and Workshop Act for the West Drayton District of the county of Middlesex.

Treves, F. B., M.R.C.S., L.R.C.P., has been appointed a Resident Assistant in the Throat Department at St. Thomas's Hospital.

Wallace, J., M.R.C.S., L.R.C.P., has been appointed a Resident Assistant in the Skin Department at St. Thomas's Hospital.

Ward, W. C. A., M.R.C.S., L.R.C.P., has been appointed Junior Ophthalmic House Surgeon at St. Thomas's Hospital.

Webb, G. L., B.C. Cantab., M.R.C.S., L.R.C.P., has been appointed a Resident Assistant in the Skin Department at St. Thomas's Hospital.

Wilson, William Cheyne, M.D. Edin., has been appointed Honorary Physician to the Devon and Cornwall Certificated Industrial School for Girls, Plymouth.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

Ayr District Asylum.—Senior and Junior Assistant Physicians, at £150 and £120 respectively per annum, with board, apartments, laundry, and attendance.

Bedford County Hospital.—House Physician. Salary £80 per annum, with apartments, board, and laundry. Also House Surgeon. Salary £100 per annum, with apartments, board, and laundry.

Birmingham Asylum, Rubery-hill.—Assistant Medical Officer. Salary £150 per annum, with apartments, board, &c.

Bradford Royal Infirmary.—Medical Officer, unmarried. Salary £100 per annum, with board and residence.

Brighton, Sussex County Hospital.—Second House Surgeon, unmarried. Salary £60 per annum, with board, residence, and washing. Also House Surgeon, unmarried. Salary £100 per annum, with board and residence.

Bromyard Union.—Medical Officer.

Cancer Hospital, Fulham-road, London, S.W.—Senior House Surgeon. Salary £80 per annum.

Cardiff Union Workhouse.—Assistant Medical Officer, unmarried. Salary £150 per annum, with rations, apartments, attendance, and washing.

Chorlton and Manchester Joint Colony for Epileptics, Langho, near Blackburn.—Resident Medical Officer. Salary £150 per annum, with board and residence.

Derwent Valley Water Board.—Medical Officer for Workmen's Village at Birchinlee.

East London Hospital for Children and Dispensary for Women, Shadwell, E.—House Surgeon for six months. Honorarium of £25, with board, residence, &c. Also Medical Officer for six months. Salary at rate of £100 per annum.

Eccles and Patricroft Hospital.—House Surgeon, unmarried. Salary £70 per year, with board, residence, and washing.

Egyptian Government, Ministry of Education.—Professor of Midwifery and Gynæcology. Salary £400 a year. Also Medical Tutor and Registrar to Kasr-el-Ainy Hospital. Salary £400 a year.

Enniskillen, Fermanagh County Infirmary.—House Surgeon. Salary £52 per annum.

Evelina Hospital for Sick Children, Southwark, S.E.—Clinical Assistants.

Exeter, Royal Devon and Exeter Hospital.—Assistant House Physician, unmarried. Salary £60 per annum, with board, lodging, and washing (no stimulants).

Great Northern Central Hospital, Holloway.—Pathologist and Curator. Salary £100 per annum. Also Senior House Physician, Senior House Surgeon, Junior House Physician, and two Junior House Surgeons. All for six months. Salaries of senior officers at rate of £60 per annum and of junior officers at rate of £30 per annum, with board, lodging, and washing.

Hastings, St. Leonards, and East Sussex Hospital.—House Surgeon, unmarried. Salary £75 per annum, with residence, board, and washing.

Hospital for Consumption and Diseases of the Chest, Brompton.—Physician. Also Resident House Physicians. Honorarium £25 for six months.

Huddersfield Infirmary.—Junior House Surgeon. Salary £50 per annum, with board, residence, and washing.

Leicester Infirmary.—Resident Surgical Dresser for six months. Honorarium £10 10s.

Liverpool Infirmary for Children.—House Surgeon. Salary £100 per annum, with board and lodging.

Lowestoft Hospital.—House Surgeon, unmarried. Salary at rate of £80 per annum, with board, lodging, and washing.

Manchester Education Committee.—Assistant Medical Officer. Salary £200 per annum.

Manchester, University of.—Junior Demonstrator in Physiology. Salary £100, rising to £150 per annum.

Middlesbrough, North Riding Infirmary.—House Surgeon, unmarried. Salary £100 per annum, with residence, board, and washing.

Northampton General Hospital.—Assistant House Surgeon. Salary £50 a year, with apartments, board, washing, and attendance.

North-Eastern Hospital for Children, Hackney-road, Bethnal Green, E.—House Surgeon for six months. Salary at rate of £60 per annum, with board, residence, and laundry.

North-West London Hospital, Kentish Town-road. — Second Honorary Anæsthetist.

Oldham Infirmary.—Senior House Surgeon. Salary £100 per annum, with board, residence, and washing.

Royal London Ophthalmic Hospital, City-road, E.C.—Senior House Surgeon. Salary at rate of £100 a year, with board and residence.

St. Pancras and Northern Dispensary, 126, Euston-road.—Resident Medical Officer, unmarried. Salary £105, with residence and attendance.

Sheffield Royal Hospital.—Resident Medical Officer, unmarried. Salary £50 per annum, with board and lodging.

Sheffield Union Hospital.—Resident Medical Officer. Salary £100 per annum, with apartments, rations, and allowances.

Shrewsbury, Salop Infirmary.—House Physician for six months. Salary at rate of £50 per annum, with board and apartments. Also House Surgeon, unmarried. Salary £100 per annum, with board, washing, and residence.

Victoria Hospital for Children, Tite-street, Chelsea, S.W.—House Surgeon for six months. Honorarium of £25, with board and lodging.

West Bromwich District Hospital.—Resident Assistant House Surgeon, unmarried. Salary £50 per annum, with board, residence, and washing.

West London Hospital, Hammersmith-road, W.—Two House Physicians and Three House Surgeons for six months. Board, lodging, and laundry.

Births, Marriages, and Deaths.

BIRTHS.

Colman.—On Sept. 8th, at Wimpole-street, W., the wife of W. S. Colman, M.D., F.R.C.P., of a son.

Houseman.—At Aberdeen, on Sept. 6th, the wife of Edward Houseman, M.B., B.C. Cantab., *East India* Railway, of a daughter.

McDougall.—On Sept. 5th, at Benloyal, Woodcote-road, Wallington, Surrey, the wife of William Stewart McDougall, *M.B., C.M., of a* daughter.

Mornement.—On Sept. 8th, at Eastney Barracks, Portsmouth, the wife of Staff-Surgeon R. H. Mornement, of a son.

Webb.—On Sept. 7th, at Northleach, the wife of Captain H. G. Stiles Webb, R.A.M.C., of a daughter.

Whitfield.—On Sept. 9th, at Bentinck-street, W., the wife of Arthur Whitfield, M.D., F.R.C.P., of a son.

MARRIAGES.

Geddes—Ross.—On Sept. 8th, at St. Mary's, Livingston, Staten Island, New York, A. Campbell Geddes, M.B., Ch.B., to Isabella Gamble, daughter of W. A. Ross.

Head—Roos.—On Sept. 6th, at St. John's Church, Croydon, Timothy John Head, M.R.C.S., L.R.C.P., to Florence Adelaide May, daughter of G. C. W. Roos.

DEATHS.

Adams.—On Sept. 6th, at Hove, James Adams, M.D., M.R.C.S., in his 77th year.

Barker.—On Sept. 3rd, at Aldeburgh, Suffolk, Gordon Campbell Barker, M.D., aged 40 years.

Smith.—On Sept. 5th, Leslie Ernest Maule Smith, M.R.C.S., L.R.C.P., aged 24 years.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

REFUSE IN THE STREETS.

On August 13th the following by-laws of the London County Council came into force:—

Waste paper, refuse, advertising bills, fruit rinds, broken glass, &c.

No person shall (1) sweep or otherwise remove from any shop, house, or vehicle into any street any waste paper, shavings, or other refuse, or being a costermonger, newsvendor, or other street trader, throw down and leave in any street any waste paper, shavings, or other refuse; (2) throw down and leave in any street, for the purpose of advertising, any bill, placard, or other substance; (3) throw down and leave in any street any bill, placard or other paper which shall have been torn off or removed from any bill-posting station.

No person shall deposit in any street or public place to the danger of any passenger, the rind of any orange banana, or other fruit, or the leaves or refuse of any vegetable.

No person shall throw, place, or leave any bottle or any broken glass, nail, or other sharp substance (not being road material) on or in any street or public place in such a position as to be likely to cause injury to passengers or animals or damage to property.

In these by-laws the expression "street" includes any highway, and any road, bridge, lane, path, footway, mews, square, court, alley, or passage to which the public have access for the time being.

Any person who shall offend against any of these by-laws shall be liable for each offence to a fine not exceeding 40*s*.

The by-laws made by the Council on May 12th, 1903, relative to the throwing down in streets of waste paper, refuse, advertising bills, broken glass, &c, are repealed as from the date on which the above by-laws come into force.

These by-laws are most excellent if only they are acted upon, but by-laws have a way of becoming ignored. There are still plenty of alternating electric light signs to be seen, despite a by-law of the County Council passed forbidding them some years ago; and the "Winner" yeller is still abroad in the land despite an edict of the County Council and of the Commissioner of Police. However, the above by-laws show a desire that the streets of London should be made less filthy. Piccadilly-circus is usually strewed with banana skins, posters of newspapers, omnibus tickets, and dirt of various kinds. A few arrests by the police and a few convictions with the full fine imposed by magistrates will presumably alter this state of affairs; but as yet the by-laws of the County Council appear to be only nominally in force.

THE INFECTIVITY OF TYPHOID FEVER.

To the Editors of The Lancet.

Sirs,—Can any of your readers inform me whether, and if so for how long, the bacillus typhosus is present in the excreta *after* convalescence has set in, and arising therefrom, and for what length of time, if at all, is it wise to disinfect the stools and urine after convalescence from typhoid fever is well established?

I am, Sirs, yours faithfully,

Sept. 10th, 1906. S.

PRINCIPALS, LOCUM-TENENTS, AND MEDICAL AGENTS.

To the Editors of The Lancet.

Sirs,—As an agent of 30 years' standing may I be permitted to enter my protest against "Retrospect's" condemnation of agents who do not charge "a uniform fee of half a guinea to each side." Your correspondent's experience appears to be limited to his engagements as locum during three years; allowing him, say, 20 engagements each year, it would give him 60 experiences as locum, and if he took a holiday every year during the 23 years he was a principal we can credit him with 23 experiences. Seeing that the medical profession numbers some 38 000 members, and that probably more than half these require a locum-tenent at least once a year, his experiences during 23 years represent but an infinitesimal proportion of the total. I have tried both systems, and before adopting the plan of not charging a fee to the principal I consulted many on the point and they were unanimous in the opinion that it seemed rather hard on those who were offering engagements at a fair salary to have to pay a fee, seeing that they could get what they wanted at their hospital, or by an advertisement in the medical papers, without going to an agent at all. A good locum-tenent, on the contrary, is only too glad to be kept in constant employment by his agent and pay a fair fee for each engagement. I have effected many thousands of such engagements, charging no fees to principals, and fees varying from 2*s*. 6*d*. to 10*s*. 6*d*. to locums, according to length of engagements (and in exceptional cases where the engagement is very long or at special fees a maximum fee of 21*s*.) I am glad to be able to assert that on an average I do not get one complaint a year from the locum-tenents as to the fee being excessive, nor do I find principals complain of the gentlemen supplied. The best proof of satisfaction is, perhaps, the fact that my locum-tenents hardly ever leave me, except to settle in practice, an that the same principals apply to me repeatedly for the same man as good a one as they had last time.

I am, Sirs, yours faithfully,

Percival Turner.

Adam-street, Adelphi, W.C., Sept. 11th, 1906.

◆

Adenoid.—An English medical man holding British qualifications i permitted to practise in Belgium without passing any examination but he is required to obtain the written permission of the Belgia Secretary of State for Home Affairs. With regard to France th foreign medical practitioner stands upon exactly the same footin as a French medical practitioner—i.e, he must pass exactly th same examinations as a native Frenchman who desires to practis medicine has to do, and no degree or diploma which he may posse is allowed for in any way, or will excuse him from any of th French examinations. Our correspondent will find full information as regards France at p. 629 of The Lancet of Sept. 1st.

Anonymous.—1. The wording of the deed of partnership, i.e., the clauses, if any, defining what work should and what should not be considered as coming under the partnership, will decide the matter. If the work in question cannot be brought under the clauses of the deed the point should be made a matter of friendly arrangement between A and B. 2. A and B should not demand fees. The patient should pay them to D on his return, when D should hand them over to A and B. If no fees are tendered D can send in his bill in the usual way and pay the amount over to A and B.

Noise.—Our correspondent will find the law as to nuisances and their abatement by public authorities laid down in Section 91 *et seq.* of the Public Health Act of 1875, but the case is probably more in the nature of a private wrong. We cannot express any opinion as to the legal points involved, in regard of which he is advised to consult a solicitor who can refer to cases in the authorised Law Reports and advise our correspondent as to his remedy (if any), which may be by application to the High Court for injunction. We know of no book on this subject.

Dunstable.—A private house need not be licensed for the reception of a single lunatic patient. Such a patient must, however, be received under the usual reception order and a report on his physical and mental health has to be sent within a month to the Commissioners in Lunacy as they may require. We are not aware whether the Commissioners give information readily to those intending to do as our correspondent proposes, but a letter to the secretary would bring information. A copy of the Lunacy Act, 1890, can be obtained through a bookseller.

Hirsutus (Medicus).—The substance mentioned is an active depilatory. It should be freshly prepared, as if kept it is not unlikely to oxidise into sulphate. If used in the form of paste it is just spread on the hairy skin. If in the form of powder it must be mixed into a cream with water. Caution is necessary in using it on delicate skins, for it is decidedly irritating. In general the hair may be easily rubbed off after two or three minutes.

Communications not noticed in our present issue will receive attention in our next.

Medical Diary for the ensuing Week.

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY (17th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (2 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), City Orthopædic (4 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (9.30 A.M.), Royal Free (2 P.M.), Guy's (1.30 P.M.), Royal Ear (2 P.M.), Children, Gt. Ormond-street (3 P.M.).

TUESDAY (18th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), West London (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (1 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Soho-square (2 P.M.), Chelsea (2 P.M.), Central London Throat and Ear (2 P.M.), Children, Gt. Ormond-street (2 P.M., Ophthalmic, 2.15 P.M.).

WEDNESDAY (19th).—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing Cross (3 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), King's College (2 P.M.), St. George's (Ophthalmic, 1 P.M.), St. Mary's (2 P.M.), National Orthopædic (10 A.M.), St. Peter's (2 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Gt. SATURDAY (22nd).—POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—10 A.M.: Diseases of the Throat. Nose and Ear. 2 P.M.: Medical and Surgical Clinics. 2.30 P.M.: X Rays. Operations.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

THE Index to Vol. I. of 1906, which was completed with the issue of June 30th, and the Title-page to the Volume, were given in THE LANCET of July 7th.

VOLUMES AND CASES.

VOLUMES for the first half of the year 1906 are now ready. Bound in cloth, gilt lettered, price 18*s*., carriage extra.

Cases for binding the half-year's numbers are also ready. Cloth, gilt lettered, price 2*s*., by post 2*s*. 3*d*.

To be obtained on application to the Manager, accompanied by remittance.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.				TO THE COLONIES AND ABROAD.			
One Year	£1	12	6	One Year	£1	14	8
Six Months	0	16	3	Six Months	0	17	4
Three Months	0	8	2	Three Months	0	8	8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and Agents are authorised to collect, and generally do so collect, from the Proprietors the cost of such extra postage

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied. Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND.

METEOROLOGICAL READINGS.

An original and novel feature of "THE LANCET General Advertiser" is a Special Index to Advertisements on pages 2 and 4, which not only affords a ready means of finding any notice but is in itself an *additional* advertisement.

Answers are now received at this Office, by special arrangement, to advertisements appearing in THE LANCET.

The Manager cannot hold himself responsible for the return of testimonials, &c., sent to the Office in reply to Advertisements; copies only should be forwarded.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Office, 423, Strand, London, to whom all letters relating to Advertisements or Subscriptions should be addressed.

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France—J.

A Lecture

ON

PHARYNGEAL ABSCESSES.

Delivered at the Hospital for Sick Children, Great Ormond-street, London, W.C.,

BY GEORGE E. WAUGH, B.A. CANTAB., M.D., B.S. LOND., F.R.C.S. ENG.,
ASSISTANT SURGEON TO THE HOSPITAL.

GENTLEMEN,—Abscesses in the pharynx are of perpetual interest on account of the difficulty in detecting their presence in the early stages of their formation, and of the danger which attends the failure to do so. Perhaps the fact that in very young children the symptoms are seldom referred directly to the site of the lesion is one reason why they are so frequently overlooked at the onset. Nor can the mother—who as a rule is an accurate observer and interpreter of the cause of symptoms of illness in her child—shed much light upon the trouble. She is generally deceived to the extent of completely, misinterpreting the symptoms in these cases and mistakes the reluctance of the child to swallow for "vomiting," "loss of appetite," "cough," "bronchitis," "teething," and many other disorders with which she is familiar. Such a history must have some slight tendency to prejudice the view that is taken of the case at the beginning, especially since many of the symptoms of a pharyngeal abscess in the earliest stage are common to it and these other disorders. In many cases the onset of some acute specific illness may be suspected—a suspicion rightly founded when the early symptoms are so frequently those of a toxæmia. To include a certain type of these abscesses in the list of acute specific disorders is at any rate an aid to the making of a differential diagnosis of great value to the patient, although it may not be a correct application of the term from the standpoint of pathology. But it is of far greater importance to remember that in the routine examination of a child who is obviously ill and in whom the symptoms and physical signs are ambiguous and not mutually explanatory an examination of the pharynx must be included. By such means only will the inflamed area in the pharynx be detected in its earliest stage. The extreme importance of this procedure lies in the fact that the best treatment of pharyngeal abscesses is to prevent them, and only by the application of suitable forms of treatment at this stage is prevention possible.

Pharyngeal abscesses may be divided into two classes, tuberculous and non-tuberculous, and the latter class may be subdivided into intra-pharyngeal abscesses and extra-pharyngeal abscesses according to the situation of the primary focus of infection either within the walls of the pharynx or outside of them.

1. *Tubercular pharyngeal abscesses.*—These are the only abscesses of the pharynx which arise in the middle line of the posterior wall of the pharynx and spread outwards. They are found in cases of tuberculous disease of the cervical vertebræ and their mode of onset is insidious. In consequence it is of great importance to examine the pharynx at regular intervals in these cases. Inspection alone is valueless and must be followed by palpation. If this procedure has been neglected an abscess may have attained considerable size before symptoms appear which compel attention to the pharynx. By this time superficial ulceration of the pharyngeal wall may have already begun and consequently the risk of a secondary infection being grafted upon a purely tuberculous lesion has been intensified. Dysphagia is generally the symptom that first appears but by the time that it has done so the abscess as a rule has already attained a considerable size.

The treatment must be carried out strictly on those surgical principles which govern the treatment of all tuberculous lesions and especially those in connexion with bone. The avoidance of all secondary infection is the predominant factor in determining a successful result, and therefore these abscesses must always be opened by an incision in the neck. The lining membrane must be removed methodically by a sharp spoon, not by haphazard scraping. Enlarged glands in the neck must be dissected out and the wound closed. A drainage-tube may be inserted for 24 hours. It is seldom one's fortune to be able to remove a sequestrum from the bodies of the vertebræ by these means. Only occasionally does it happen so and therefore the abscesses tend to recur. But by a repetition of these procedures at the earliest sign of recurrence a cure generally results.

2. *Non-tubercular abscesses.*—(*a*) Intra-pharyngeal abscesses of non-tuberculous origin and in which the primary site of the lesion is on the internal surface of the pharynx arise invariably as the result of some inflammatory affection of the tonsil. They have been described as arising spontaneously or as the result of trauma from swallowing some hard substance or from an infection in the post-pharyngeal tonsil or in lymphatic glands which lead a mythical existence upon the bodies of the cervical vertebræ. Further, they have been described as starting in the middle line of the posterior pharyngeal wall. The only kind of abscess that does start there is the tubercular one in association with caries of the spine. These others always start on the side wall of the pharynx immediately behind one posterior pillar of the fauces; they spread backwards along the lateral wall of the pharynx until they reach the posterior wall, when they spread inwards towards the middle line which they cross and sometimes spread round the opposite lateral wall of the pharynx until they nearly reach the other tonsil. But even in the case of the largest abscess it is generally possible to appreciate by means of the finger that on one side there is no groove between the tonsil and the abscess, whilst on the other side towards which the abscess is spreading there is generally a groove between the advancing edge of the abscess and the other tonsil. It is exceedingly rare for this class of abscess to point externally in the neck, since it is far easier for them to track round or in the pharyngeal wall and then bulge forwards into the cavity of the oral part of the pharynx. If a pharyngeal abscess points externally in the neck it almost always belongs to the class of extra-pharyngeal abscesses, in which the abscess has originated from a suppurating gland in the neck. These abscesses may be divided into stages according to the symptoms they cause. In the very earliest stage they give rise to no particular group of symptoms. They are then found to exist as small, hard, rounded swellings in the side wall of the pharynx immediately behind a posterior pillar of the fauces. They can easily be felt and very frequently can be seen. The tonsil immediately in front of them is slightly pushed forwards; there is no groove between it and the indurated swelling and the tonsil is generally hypertrophied and ulcerated. They will only be discovered at this stage as the result of a routine examination of a child who is ill and in whom the cause of the illness is obscure—an obscurity which is frequently illuminated by careful examination of the pharynx. It is at this stage that their further development may be arrested by appropriate treatment. In the next stage the group of symptoms indicate, as a rule, that the site of the lesion is in the pharynx. The child has a characteristic "muffled cry," he is frequently soaked by saliva which he dribbles rather than suffer pain from swallowing it, and the head is thrown back so that the opening of the larynx shall not be occluded by the abscess in the forward position. He has an obvious difficulty in swallowing, which the mother may describe as "vomiting," or even "coughing," and the profuse salivation often leads her to suspect "teething." There are, as a rule, no enlarged glands in the neck, or the enlargement is only a slight one. Finally the abscess can be both felt and seen—at this stage it is a tense elastic swelling. As the swelling increases in size the third stage is reached which is characterised by all the signs and symptoms of obstructive dyspnœa. It is in this stage that the condition has been mistaken for diphtheria with laryngeal involvement, tracheotomy has been performed without any relief to the symptoms, and a fatal issue has speedily ensued. Such a mistake can only be avoided by adhering rigidly to the rule of examining the pharynx with the finger in all cases of obstructive dyspnœa. Inspection of the pharynx is difficult in small children and even when membrane can be seen on the tonsils it is necessary to exclude the presence of a pharyngeal abscess by palpation, since it can co-exist with diphtheria and may not infrequently be found to be present in an early stage of formation. In obstructive dyspnœa caused by a pharyngeal abscess "stridor" and "croup" are not generally present. These are valuable signs for differentiating the condition from laryngeal diphtheria.

(*b*) When the deep lymphatic glands of the neck are enlarged under certain conditions they push the side wall of the pharynx inwards. If the gland which is nearest to the pharyngeal wall has already broken down it will form a tense, rounded, elastic swelling bulging into the oral part of the pharynx. It has, therefore, all the appearances of a pharyngeal abscess, but from its mode of origin it is extra-pharyngeal. (The glands in the neck may have enlarged as the result of a purely tuberculous infection, but as a rule the infection is a mixed one and therefore this type of abscess is not classed with those arising from caries of the spine.) It is clear from the mode of its formation that it must always be preceded by an enlargement of glands in the neck, which has persisted for some considerable time. It ought to be detected as the result of a routine examination of the pharynx before it has had time to give rise to characteristic pharyngeal symptoms. Evidence of softening of enlarged glands in the neck is always carefully watched for in those glands immediately underlying the skin. It is of equal importance to watch for it in those glands which lie close to the wall of the pharynx.

The most satisfactory treatment of intra-pharyngeal abscesses is to prevent their formation. This can only be done when they are detected in the first stage of their formation as a small indurated mass behind a posterior pillar of the fauces. The throat must then be syringed at short intervals with an alkaline lotion and the ulcerated surface of the tonsil painted with a solution of salol in glycerine, or with compound tincture of benzoin, or with any of the usual applications for inflammatory conditions of the throat. A mixture containing chlorate of potassium and salicylate of sodium given every few hours further aids in keeping the mouth and throat clean. The patient must be kept upon a strictly fluid diet. In many cases the adoption of these measures leads to the disappearance of the indurated mass within five or seven days. As soon as all signs of acute inflammation have disappeared the tonsils must be removed completely by enucleation and so the future formation of an intra-pharyngeal abscess rendered practically impossible. In several hundreds of cases in which this procedure has been adopted so far no case has appeared again with an intra-pharyngeal abscess, whilst in those in which an abscess had already formed before they came under my observation there was not one from which the tonsils had been previously removed.

When an abscess has already formed immediate operation is the only treatment. The consideration as to whether the abscess is of intra-pharyngeal or extra-pharyngeal origin will determine the controversy as to whether it should be opened through the neck or through the mouth. No one would seriously advocate the opening of a quinsy through the neck nor would they advocate the evulsion of enlarged glands from the neck through an opening in the mouth.

Intra-pharyngeal abscesses can only be successfully treated by an incision made through the inner wall of the pharynx and extra-pharyngeal abscesses by an operation through the neck. In the former case an anæsthetic must be given unless the patient is already moribund from obstructive dyspnœa. A sand-bag must be placed under the shoulders so that the head falls backwards sufficiently to form an inclined plane down which the pus can travel towards the naso-pharynx and yet does not form so great an inclination as to cause a congestion of the pharyngeal plexuses of veins. A guarded scalpel must be used and with the index finger of the left hand as a guide an incision must be made extending over the whole length of the abscess cavity. Unless this is done a pocket will be left at the lower end which cannot be drained properly and will be a fruitful source of future complications. If the abscess is very large it is impossible to make the incision along the whole length of it by one cut. The pus must be evacuated through a small opening, so that the tumour partially collapses, and then the incision can be extended to its proper length. The operator must stand behind the patient's head and the direction of the cut must be from below upwards. The most suitable after-treatment for these cases is to syringe the back of the throat frequently with an alkaline lotion, keep the patient on liquid food, and give a mixture containing chlorate of potassium and salicylate of sodium. Most cases are quite well within from five to seven days after the operation.

An extra-pharyngeal abscess must be opened externally through the neck. The operation to be successful involves the complete removal of all the enlarged glands and from the position of the abscess these have generally to be removed before the abscess is reached. The direction of incision must be so planned that all the glands from the anterior and posterior triangles of the neck can be removed if necessary. When the abscess has been opened the cavity must be dissected away from the surrounding structures as far as possible and when dissection is impossible the lining membrane must be carefully removed by a sharp spoon. After well washing with a sterilised saline solution the wound in the neck must be stitched up. A small drainage-tube may be inserted with advantage for 24 hours. In nearly all cases if the infected glands have been adequately removed healing takes place by first intention.

These methods have been applied to 25 cases of pharyngeal abscesses, excluding those arising from caries of the spine. In this series there was one death. The child was moribund from obstructive dyspnœa when admitted to the hospital and died from sudden syncope on the operation table. The remaining 24 cases have all been discharged well, those suffering from an intra-pharyngeal abscess within about a week from the date of operation and those suffering from an extra-pharyngeal abscess within about a fortnight from the date of operation. There has not been a single instance among them of those dreaded complications—septic pneumonia, septic mediastinitis, bronchitis, or a fistula in the neck. Such complications probably arise from failure to recognise the type of abscess in each case and therefore the appropriate site of operation is not chosen.

OBSERVATIONS ON THE ARTERIAL BLOOD PRESSURE IN HEART DISEASE.

BY HUBERT J. STARLING, M.D. LOND., D.P.H. CANTAB.

WHATEVER the prime lesion may be, the morbid effects of heart disease must be ascribed to failure of the heart pump—i.e., to a deviation from the normal of the mechanical conditions of the circulation. Since of these conditions the arterial blood pressure is the most important, all the complex reactive mechanisms being devoted to its maintenance, it is curious that few observations have been made on the state of the arterial blood pressure in cases of failure of compensation in heart disease. The only work on the subject with which I am acquainted is *Clinical Observations on Arterial Blood Pressure*,[1] and so far as I am aware no connected study of the whole subject has yet been made. The scattered observations which I have to bring forward in this paper may therefore serve as a stimulus to other inquiries in the same subject and may induce others to use the determination of arterial pressure as a means of diagnosis and probably a guide for treatment in cardiac disorders.

The classical signs of failure of compensation in heart disease include feeble or irregular pulse, low arterial tension, high venous pressure with backward effects leading to disorders of the abdominal viscera, and the production of œdema or ascites. When with these accepted signs of failure of compensation in man we attempt to imitate the conditions experimentally we are met at once by the difficulty, on which Cohnheim laid so much stress, of producing similar conditions in animals. It would seen simple to imitate aortic stenosis by partial ligature of the aorta. Cohnheim pointed out that the compensatory power of the heart muscle was so complete that such a ligature produced no effects whatever on the arterial pressure, the ventricles simply contracting with increased force in order to maintain the arterial pressure at its normal level. If the arterial stenosis were still further increased the heart, after one or two ineffective beats, would fail altogether. The rule in the heart appeared to be normal arterial pressure or no circulation at all. Owing to the impossibility of producing, by damage to the valves or by constriction of the arterial orifices, a condition of things which could be regarded as analogous to failure of compensation in heart disease, Cohnheim had recourse to the device of hampering the diastole of the heart by injection of oil into the pericardium.

---

[1] R. R. Stawell: International Medical Journal of Australasia, vol. x., No. 7.

This method was also used by E. H. Starling,[1] who studied the changes thereby induced both on arterial and venous pressures and showed that the result of such interference, so long as the pericardial distension allowed any circulation to occur at all resulted in a lowering of the arterial pressure and a rise of pressure in the great veins near the heart, including those of the liver. In the limbs, however, there was a fall both of venous and capillary pressures, so that it was impossible to account for the mechanical production of œdema by simple mechanical interference with the pumping action of the heart.

A study of the arterial pressure in cases of failure of compensation in man shows that there is no analogy between such cases and the case studied by Cohnheim. The injection of oil into the pericardium may be used as a means of study of the circulatory conditions in pericardial effusion, but has no bearing on cases of heart disease due to lesions of the valves or secondary to arterial conditions. In these the conditions are much more complex. Interference with the pumping action of the heart induces a whole cycle of consecutive changes, many of which are reactive in character and adapted to the neutralisation of the effects of the heart failure itself and which involve a number of different organs.

Methods.—I have used throughout this series of observations Dr. C. J. Martin's modification of the Riva Rocci manometer. This is extremely simple in design and the methods of its use are easily acquired. In regard to observations on individuals not confined to bed I have made them rest in a sitting posture for from five to ten minutes before taking their blood pressure and nearly all the observations of this series were taken between 10 A.M. and 1 P.M. The arm which is being utilised is kept at rest on a table which brings it nearly to the level of the patient's heart. In the case of those confined to bed I have endeavoured as far as possible to take the successive observations at the same time and under exactly similar conditions on each occasion. For instance, since I prefer to have the arm bare which I am going to employ the patient removes his jacket and slips up the vest and shirt and then rests for five minutes to get over any exertion entailed in this process. I find that on the first occasion of estimation it is best to repeat the process of observation some three or four times until two successive readings are more or less identical. I take the last reading as correct when the patient's excitement or timidity has subsided. It is essential that the arm should rest in a comfortable position, as any muscular contraction tends to increase the resistance offered to the obliterating force and consequently gives a wrong estimation. Where observations are being taken on a case of intermittent or irregular heart I have always taken the maximal beat as being the true indication of the force against which the heart has to work; the intervening beats which fail to "come through" I regard as evidence of incompetence. It sometimes occurs that the obliterating pressure observed as the air is being pumped into the apparatus does not coincide with the pressure at which the pulse is again perceptible when the air is allowed to escape, and in this case I take the mean of the two observations as the estimation of the maximal blood pressure.

The arterial pressure in normal individuals.—Before we can draw any conclusions from observations in cases of heart disease we must have some idea of the variations of pressure which can be regarded as normal at any given age. I have been able to obtain information on this point from a series of observations made by Dr. Martin, the results of which he kindly placed at my disposal, from the paper by Stawell, as well as from observations made by myself on a number of normal individuals, as well as on others in whom there was no circulatory disorder. Up to 40 years of age the normal systolic pressure of a patient sitting quietly and free from any emotion may vary from 100 to 120 millimetres of mercury. This pressure can be markedly increased as the result of exertion, by rigidity of the muscles, or by excitement, any of which may raise the pressure 20 to 30 millimetres of mercury. It is therefore important to insure that such disturbing factors are absent in taking the arterial blood pressure in cases of disease. With increasing age above 40 years there appears to be increasing height of arterial pressure and in extreme old age we may observe pressures as high as 200 millimetres of mercury or more. Since, however, one of the most frequent causes of death in old people is by rupture of arteries or by heart failure, it is difficult to be certain how great a rise of pressure we should regard as normal and whether, indeed, under the most favourable conditions it might not be possible to maintain throughout life an arterial pressure corresponding to that which is normal for the young adult. In a few cases at any rate in old people I have observed pressures differing but little from that found in younger patients. A few of these might be quoted here. The blood pressure averages I have estimated are as follows: From 15 to 40 years, 119·3 millimetres of mercury; from 41 to 60 years, 141·7 millimetres of mercury; 61 years and over, 154·8 millimetres of mercury. A few striking examples of advancing age with little increase of blood pressure are: 1. C——, aged 60 years; robust old fellow; blood pressure 118. 2. E——, aged 46 years; healthy and robust; blood pressure (*a*) 128, (*b*) 122·5. 3. A——, aged 56 years; robust but dyspeptic; blood pressure 131. 4. L——, aged 47 years; healthy, not vigorous; blood pressure 120. 5. C——, aged 71 years; well-nourished old man; blood pressure 142. 6. S——, aged 77 years; robust old fellow; blood pressure 138.

Whether or not we regard a rise of pressure as a necessary concomitant of advancing age it is extremely difficult to make an average blood pressure for each age, owing to the increasing frequency among our cases at advancing ages of cases with an abnormally high arterial tension in whom sooner or later this raised tension will give rise to injurious effects. Professor T. Clifford Allbutt has already drawn attention to the importance of this class of case and I shall have to deal more fully with it in a later part of my paper.

The blood pressure in heart disease.—Perhaps the most striking fact which has resulted from my determinations is that, however bad the patient, however ineffective the work of the heart pump, in no case of heart disease ordinarily so called have I ever found an arterial pressure below normal. In the diseased man, as in the healthy experimental animal, the adaptive mechanism of the circulatory system is directed to the maintenance of a normal arterial pressure, and this will only fail when the heart is unable to beat any more—i.e., here, as in experiments on animals, the heart maintains the normal pressure or stops beating altogether.

The cases of heart disease proper—i.e., those in which there has been some lesion of the auricular, ventricular, or arterial orifices—may be divided into two main classes. Class I., those in which the arterial pressure is normal (from 100 to 125 millimetres of mercury); Class II., those in which the arterial pressure is considerably above normal (from 130 to 280 millimetres of mercury). As we shall see, both classes involve lesions either of the aortic, mitral, or tricuspid orifices. They differ, however, considerably in their etiology and therefore in the indications for their proper treatment.

Class I.—This class includes all kinds of heart lesions. In every case except one, however, it will be noticed that there was a history of an antecedent attack of rheumatism, which can be regarded as the prime cause of the heart disease. I give here a short account of some of these cases.

CASE A.—A female, aged 29 years, married. She had had acute rheumatism at 25 years. She had had three children, the last being born at sixth month of pregnancy, five months before admission to hospital. On admission she had to sit up in bed and was very dyspnœic; she was very anæmic. Heart enlarged; at apex a presystolic murmur and hard first sound could be heard; over aortic area a well marked systolic murmur could be heard. No œdema or ascites. Blood pressure from 106 to 122 millimetres of mercury; approximated chiefly to latter figure towards the end of her stay in hospital. Diagnosis: mitral stenosis, probably aortic stenosis.

CASE B.—A female, aged 19 years; single. She had had rheumatic fever at 13 years. She was "quite well" except for a bad cough until a fortnight before [illegible] lesion she was a thin anæmic girl, dyspnœa [illegible] ites or œdema. Apex beat was external to [illegible] interval which was chiefly occupied by a presystolic murmur which ended in sharp first sound. Blood pressure was from 100 to 112 millimetres of mercury; no change during rest in bed. Diagnosis: mitral stenosis.

CASE C.—A female, aged 19 years, single. She had had chorea at five years and rheumatism at ten years of age. On admission she was dyspnœic, cyanosed, orthopnœic; had signs of backward pressure in lungs. The apex beat was in sixth intercostal space two inches external to the nipple, diffuse impulse over cardiac area and in epigastrium. Mitral systolic and presystolic bruits could be heard; pulse very irregular. Blood pressure was from 96 to 105 millimetres of mercury; no variation with treatment. Diagnosis: mitral stenosis and incompetence.

CASE D.—A female, aged 50 years. No history of rheumatism could be obtained. On admission she had passed only two ounces of urine during previous 24 hours. She was a fat, congested looking woman with much œdema of back, some œdema of legs, was somewhat cyanosed, and had a "mitral" character of facies. Heart beat feeble; apex beat could not be located; a systolic bruit could be heard over apex area. Blood pressure on admission was 104 millimetres of mercury; after ten days of a diuretic pill containing squill, digitalis, and mercury the blood pressure had risen to 150 millimetres of mercury, while the pulse had fallen from 120 to 80 per minute. The urine output during this time increased from under 5 ounces to over 50 ounces in the 24 hours. *On the tenth day*, when the patient was considerably improved, the diuretic pill was omitted and *the blood pressure sank to* 118 millimetres of mercury, where it remained until the patient's discharge from hospital, greatly benefited by rest and treatment. Diagnosis: mitral stenosis and *regurgitation* with suppression of urine.

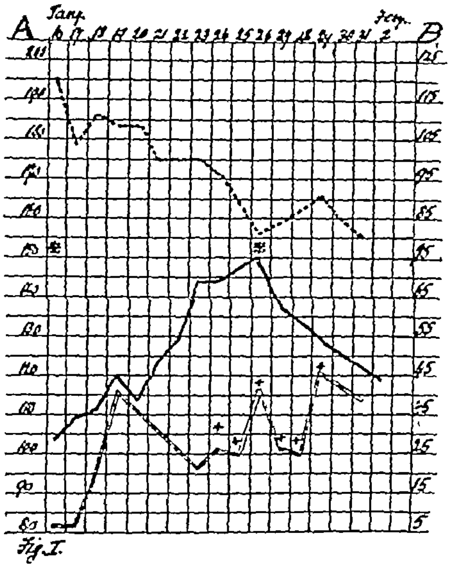
FIG. 1.



Case D, Class I., mitral regurgitation and stenosis. From * to * patient received pilula diuretica three times a day. The urine contained *no albumin*. The + signs show where some urine has been lost and the estimate is therefore lower than the correct amount. The numbers in Column A refer to the *blood pressure in millimetres of mercury*. The numbers in Column B refer to the amount of urine in ounces per diem and the pulse-rate per minute.

(N.B.—In all the charts the figures on the right-hand side of the page denote *urine in ounces per diem* and *pulse per minute*. *The figures on* the left-hand side denote blood pressure in millimetres of mercury. - - - - - - = Pulse. ———— = Blood pressure. ═════ = Urine.)

CASE E.—A male, aged 44 years, was in hospital ten years ago for aortic incompetence, and since that time had been at his regular work. He was in the boot trade, work which necessitated standing up all day and was situated up three flights of stairs. Gave up work 14 days before admission. On admission he was a well built man; he could lie nearly flat in bed without inconvenience; had a little dyspnœa and a little œdema of the legs. "To and-fro" aortic murmurs could be heard over aortic area and were transmitted down to the apex. Capillary pulsation was well marked. Blood pressure was from *122 to 136 millimetres of mercury*; pulse was 64. Diagnosis: aortic stenosis and incompetence.

Discussion of cases.—In some of these cases the heart failure was limited to the left side, so that its chief result was increased distension of the lung vessels and the consequent interference with the respiratory functions (dyspnœa and cyanosis). In others, however, the failure has extended to the right side so that there was a rise of pressure in the systemic veins and signs of backward pressure in the liver with the production of ascites and œdema. Can we form any idea of the sequence of events in such conditions? It must be remembered that the guiding factor in the circulation is the maintenance of a *normal arterial pressure*, since it is only in this way that the brain, the ruling tissue of the body, can *keep* itself supplied with the proper amount of oxygen. A temporary failure of the heart to send the proper amount of blood to the brain, whether due to abnormal reflux through the mitral valves or to an abnormal obstacle to the emptying of the left auricle, is at once followed by efforts on the *part of the* vaso-motor system to remedy the deficiency. The first result is, therefore, a constriction of all the vessels in the body, especially *those* of the splanchnic area, and as a result a rise of venous pressure and therefore of pressure in the guiding cavities of the heart—namely, the venous orifices and the auricles. The greater tension on these cavities causes increased contraction and therefore tends to restore the ventricular output to *its previous* amount. The splanchnic constriction, as E. H. Starling showed, must lead *to increased* up-take of fluids from the alimentary canal and therefore finally *to an increased volume* of fluid in the circulation. The inadequate heart muscle has to be stimulated to further activity by increased *stretching* and this stretching is attained by an increased *fulness of the venous* system, which, as the inadequacy of the heart muscle progresses, must proceed backwards from heart to veins and finally, perhaps, even to the limb capillaries. The fact that in cases such as Case D, Class I., there was *normal arterial* pressure with increased venous pressures shows that *the system* must have been over-full—i.e., that there was a plethora. *It* is worth noting that this plethora has been actually found by Houston in certain cases of uncompensated heart disease. Unfortunately, *in these cases* no measurement was made of the arterial pressure. The existence of a condition of plethora in these cases indicates that more stress may be laid upon the mechanical conditions in the production of dropsical heart disease than was imagined by E. H. Starling, though there is no doubt that the *effect* of a *high* capillary pressure must be aided in these cases by the *malnutrition* of the capillary wall consequent on its *defective blood-supply*. For although the arterial pressure is maintained at *the normal level the system* itself does not succeed in achieving a normal circulation, since the high venous pressure will tend to diminish the gradient of pressures from arteries to veins, and the constricted condition of the arterioles will lessen the rapidity of flow through the capillaries. The directing factor in the whole cycle of events is the need of the brain for a normal oxygen supply. The venous pressure being raised the normal *circulation* through the brain *could* not be attained by simply *keeping the arterial pressure* at the normal *amount*. The patient therefore *instinctively* lowers the venous pressure in the vessels, which lead the blood away from the brain, by assuming an erect position, so that the return of blood from the brain may be aided by the influence of gravity, and the high venous pressure only makes itself felt in the dependent portions of the body. This is the reason for the orthopnœa which *is* the common feature of cases of mitral disease.

Effects of deficient oxygenation.—If the orthopnœa *is not sufficient* to maintain the normal *supply* of oxygen *to brain*, as in cases where cyanosis *is well marked*, a new series of events come into play. In the first place we have the original asphyxial excitation of the vaso-motor centre and therefore a rise of arterial pressure above normal. *The* heart, which could not carry out effectively its normal work, is thus called upon to do an amount of work which is very much greater than normal, a condition of things which must evidently *lead to* rapid *exacerbation* of the *disorder* and result *finally in total failure of* the circulation. In such cases, therefore, *we may* find a pressure of 130 to 140 millimetres of mercury in the arteries, although we are not justified in placing the case with the other cases which I deal with in Class II. The temporary asphyxial nature of the raised pressure is at once seen in such cases if, by rest or by the administration of digitalis or by bleeding, we are able to restore to some degree the functions of the heart. In such a case the first *improvement in the heart's* action is shown not only by diminished *cyanosis* but by a *fall* in the arterial blood pressure. The effect of asphyxia in causing a temporary rise of blood pressure is shown very strikingly in cases of asthma. I may here quote the particulars of one such case.

Class III. (special case)—A female, aged 63 years; admitted on Sept. 27th, 1905. For seven years she had had *frequent attacks of* asthma. *On admission she* was a *small*, *very* thin, and *scraggy* woman; she sat bolt upright in bed and had great respiratory distress. Had a typical attack of bronchial asthma and was very *cyanosed*. *Progress and treatment*: *On* Sept. 28th there was no albumin in urine; respirations 28 per minute. Blood pressure was 188 millimetres of mercury. On the 29th, inhalation of *ethyl iodide* had no effect on *blood pressure* and *afforded no relief to the distress*. Blood pressure was 180 millimetres of mercury. Two minims of morphine were injected hypodermically at 9 P.M. Three minims of pinol were *given every four hours, and 10 minims of potassium* iodide, 10 minims of tincture of stramonium, and half a drachm of spirit of ether three times a day. On the 30th she was much easier and had slept the *previous night*. *Blood pressure* was 148 *millimetres of mercury*. On Oct. 2nd she was progressing well, lay flatter in bed and breathed *more* easily. Cyanosis was disappearing. Blood pressure was 118 millimetres of *mercury*. On the 3rd *blood pressure* was 112. Patient was discharged on Oct. 10th cured of the attack.

Even in *those cases* where a barely adequate supply of *oxygen to the respiratory* centre is assured by position or other regulative mechanism, a deficient circulation through the rest of the body will involve a deficient oxygenation. The blood as it circulates through all organs of the body,

cyanosed, and had a "mitral" character of facies. Heart beat feeble; apex beat could not be located; a systolic bruit could be heard over apex area. Blood pressure on admission was 104 millimetres of mercury; after ten days of a diuretic pill containing squill, digitalis, and mercury the blood pressure had risen to 150 millimetres of mercury, while the pulse had fallen from 120 to 80 per minute. The urine output during this time increased from under 5 ounces to over 50 ounces in the 24 hours. On the tenth day, when the patient was considerably improved, the diuretic pill was omitted and the blood pressure sank to 118 millimetres of mercury, where it remained until the patient's discharge from hospital, greatly benefited by rest and treatment. Diagnosis: mitral stenosis and regurgitation with suppression of urine.

FIG. 1.

The numbers in Column B refer to the amount of urine in ounces per diem and the pulse-rate per minute.

(N B.—In all the charts the figures on the right-hand side of the page denote urine in ounces per diem and pulse per minute. The figures on the left-hand side denote blood pressure in millimetres of mercury. - - - - - - = Pulse. ———— = Blood pressure. ═════ = Urine.)

CASE E.—A male, aged 44 years, was in hospital ten years ago for aortic incompetence, and since that time had been at his regular work. He was in the boot trade, work which necessitated standing up all day and was situated up three flights of stairs. Gave up work 14 days before admission. On admission he was a well built man; he could lie nearly flat in bed without inconvenience; had a little dyspnœa and a little œdema of the legs. "To and-fro" aortic murmurs could be heard over aortic area and were transmitted down to the apex. Capillary pulsation was well marked. Blood pressure was from 122 to 136 millimetres of mercury; pulse was 64. Diagnosis: aortic stenosis and incompetence.

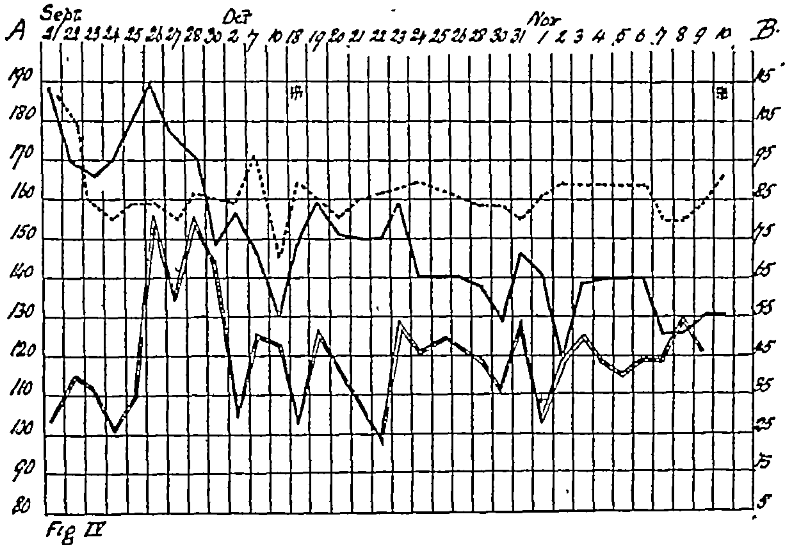
Discussion of cases.—In some of these cases the heart failure was limited to the left side, so that its chief result was increased distension of the lung vessels and the consequent interference with the respiratory functions (dyspnœa and cyanosis). In others, however, the failure has extended to the right side so that there was a rise of pressure in the systemic veins and signs of backward pressure in the liver with the production of ascites and œdema. Can we form any idea of the sequence of events in such conditions? It must be remembered that the guiding factor in the circulation is the maintenance of a normal arterial pressure, since it is only in this way that the brain, the ruling tissue of the body, can keep itself supplied with the proper amount of oxygen. A temporary failure of the heart to send the proper amount of blood to the brain, whether due to abnormal reflux through the mitral valves or to an abnormal obstacle to the emptying of the left auricle, is at once followed by efforts on the part of the vaso-motor system to remedy the deficiency. The first result is, therefore, a constriction of all the vessels in the body, especially those of the splanchnic area, and as a result a rise of venous pressure and therefore of pressure in the guiding cavities of the heart—namely, the venous orifices and the auricles. The greater tension on these cavities causes increased contraction and therefore tends to restore the ventricular output to its previous amount. The splanchnic constriction, as E. H. Starling showed, must lead to increased up-take of fluids from the alimentary canal and therefore finally to an increased volume of fluid in the circulation. The inadequate heart muscle has to be stimulated to further activity by increased stretching and this stretching is attained by an increased fulness of the venous system, which, as the inadequacy of the heart muscle progresses, must proceed backwards from heart to veins and finally, perhaps, even to the limb capillaries. The fact that in cases such as Case D, Class I., there was normal arterial pressure with increased venous pressures shows that the system must have been over-full—i.e., that there was a plethora. It is worth noting that this plethora has been actually found by Houston in certain cases of uncompensated heart disease. Unfortunately, in these cases no measurement was made of the arterial pressure. The existence of a condition of plethora in these cases indicates that more stress may be laid upon the mechanical conditions in the production of dropsical heart disease than was imagined by E. H. Starling, though there is no doubt that the effect of a high capillary pressure must be aided in these cases by the malnutrition of the capillary wall consequent on its defective blood-supply. For although the arterial pressure is maintained at the normal level the system itself does not succeed in achieving a normal circulation, since the high venous pressure will tend to diminish the gradient of pressures from arteries to veins, and the constricted condition of the arterioles will lessen the rapidity of flow through the capillaries. The directing factor in the whole cycle of events is the need of the brain for a normal oxygen supply. The venous pressure being raised the normal circulation through the brain could not be attained by simply keeping the arterial pressure at the normal amount. The patient therefore instinctively lowers the venous pressure in the vessels, which lead the blood away from the brain, by assuming an erect position, so that the return of blood from the brain may be aided by the influence of gravity, and the high venous pressure only makes itself felt in the dependent portions of the body. This is the reason for the orthopnœa which is the common feature of cases of mitral disease.

Effects of deficient oxygenation.—If the orthopnœa is not sufficient to maintain the normal supply of oxygen to brain, as in cases where cyanosis is well marked, a new series of events come into play. In the first place we have the original asphyxial excitation of the vaso-motor centre and therefore a rise of arterial pressure above normal. The heart, which could not carry out effectively its normal work, is thus called upon to do an amount of work which is very much greater than normal, a condition of things which must evidently lead to rapid exacerbation of the disorder and result finally in total failure of the circulation. In such cases, therefore, we may find a pressure of 130 to 140 millimetres of mercury in the arteries, although we are not justified in placing the case with the other cases which I deal with in Class II. The temporary asphyxial nature of the raised pressure is at once seen in such cases if, by rest or by the administration of digitalis or by bleeding, we are able to restore to some degree the functions of the heart. In such a case the first improvement in the heart's action is shown not only by diminished cyanosis but by a *fall* in the arterial blood pressure. The effect of asphyxia in causing a temporary rise of blood pressure is shown very strikingly in cases of asthma. I may here quote the particulars of one such case.

Class III. (special case).—A female, aged 63 years; admitted on Sept. 27th, 1905. For seven years she had had frequent attacks of asthma. On admission she was a small, very thin, and scraggy woman; she sat bolt upright in bed and had great respiratory distress. Had a typical attack of bronchial asthma and was very cyanosed. Progress and treatment: On Sept. 28th there was no albumin in urine; respirations 28 per minute. Blood pressure was 168 millimetres of mercury. On the 29th, inhalation of ethyl iodide had no effect on blood pressure and afforded no relief to the distress. Blood pressure was 180 millimetres of mercury. Two minims of morphine were injected hypodermically at 9 P.M. Three minims of pinol were given every four hours, and 10 minims of potassium iodide, 10 minims of tincture of stramonium, and half a drachm of spirit of ether three times a day. On the 30th she was much easier and had slept the previous night. Blood pressure was 148 millimetres of mercury. On Oct. 2nd she was progressing well, lay flatter in bed and breathed more easily. Cyanosis was disappearing. Blood pressure was 118 millimetres of mercury. On the 3rd blood pressure was 112. Patient was discharged on Oct. 10th cured of the attack.

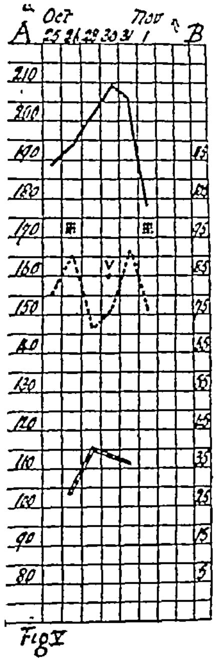
Even in those cases where a barely adequate supply of oxygen to the respiratory centre is assured by position or other regulative mechanism, a deficient circulation through the rest of the body will involve a deficient oxygenation. The blood as it c

FIG. 4



Case G, Class II.—Primary kidney; secondary cardiac lesions. From * to * one minim of liquor trinitrini three times a day, increased to two minims three times a day after one week. The numbers in column A refer to the blood pressure in millimetres of mercury. The numbers in column B refer to the amount of urine in ounces per diem and pulse-rate per minute.

FIG. 5.



Case H, Class II.—Primary kidney. Secondary heart. From * to * one minim of liquor trinitrini was given every four hours. V, blood pressure after venesection (12 ounces were removed) The numbers in column A refer to the blood pressure in millimetres of mercury. The numbers in column B refer to the amount of urine in ounces per diem and rate of pulse per minute.

CASE E.—A man, aged 56 years. He was at work until three weeks before admission. No history of rheumatism; alcoholic history uncertain. On admission on August 12th, 1905, he was a large strongly built man; dyspnœic; very irregular pulse; heart much enlarged with many bruits; slight œdema of legs. He was discharged improved on Sept. 8th but readmitted on Oct. 15th, having been back to work. He had œdema of legs, ascites, very intermittent and irregular pulse, and was very dyspnœic. A trace of albumin was in the urine. Discharged on Nov. 11th improved. Diagnosis: mitral and aortic incompetence. The blood pressure in this case was 120 millimetres of mercury on admission, when the heart was obviously unable to carry out the task required of it. After three days' administration of diuretic pills (containing squill, mercury, and digitalis), the blood pressure rose to 170 millimetres of mercury, and kept between this level and 160 millimetres until the pill was discontinued, when it sank to 140 millimetres, where it remained until patient's discharge.

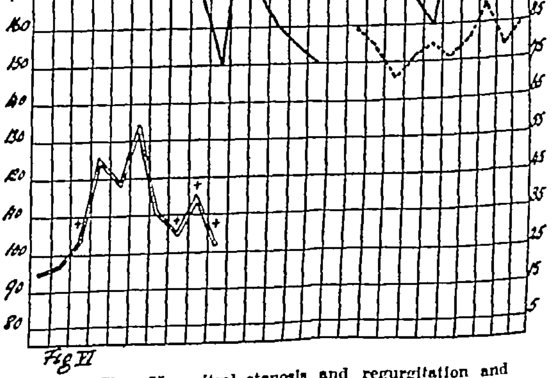
CASE F.—A man, aged 60 years. No history of rheumatism; he had been addicted to alcohol; he had had an attack of hemiplegia two and a half years ago from which he recovered after three months. On admission he was a stout flabby man, very cyanosed, and dyspnœic; he had much œdema of face, trunk, and limbs, marked ascites, and an enlarged prostate which had given him difficulty in micturition for some time past. Heart: apex beat heaving, irregular, external to nipple; loud systolic apical murmur and an aortic diastolic. Very little progress was made and the patient died after getting into a general pyæmic condition two months after admission.

CASE G.—A female, aged 41 years. No history of rheumatism; she had had dyspnœa for past two years. She had had five children (two dead) and was very bad during last pregnancy (youngest child was 15 months old). She had been getting worse lately and unable to do her work. On admission she was a thin, sallow woman; she lay in a semi-prone position; slight occasional hæmoptysis; some œdema of legs. Apex beat was in sixth space below nipple. Had reduplicated second sound over pulmonary area; loud systolic bruit over sternum at level of third costal cartilage and laboured first sound at apex. These sounds changed to definite presystolic and sharp loud first sound at apex, systolic bruit over tricuspid area, and systolic bruit over third right costal cartilages. Aortic second sound was soft. Some albumin in urine. Patient was discharged after seven weeks in hospital greatly improved in condition and with no albumin in the urine. Diagnosis: aortic stenosis, slight regurgitation; mitral stenosis, tricuspid regurgitation.

CASE H.—A female, aged 65 years. She was quite well up to 5 P.M. on the day of admission, when she was found clinging to a chair for support, and her friends noticed that her right side was paralysed. Very alcoholic history. On admission there was no loss of consciousness. Slight movement was obtainable in the right side, arm, and leg, but there was paralysis of the right side. Heart large; impulse in fifth space external to nipple, heaving in character; soft systolic bruit at apex. Hard second sound over aortic and pulmonary areas. Vessels hard and tortuous. Urine loaded with albumin. Patient insisted on leaving hospital against advice.

CASE J.—A male, aged 72 years. He was a hard drinker some years ago but since then had been a temperance lecturer and evangelist. He had suffered from dyspnœa for 18 months past. On admission on Jan. 16th he was a thin, wiry man, very dyspnœic; some œdema of legs. Pulse was very rapid and intermittent. Systolic and presystolic murmurs at apex. Radial artery very tortuous and hard. Large right pleural effusion. Patient was aspirated (right chest) three times when in hospital and was discharged after a stay of six weeks, somewhat relieved. After a fortnight he was readmitted in a much worse condition on Feb. 28th. He remained in hospital and was again aspirated and was discharged relieved on March 29th.

FIG. 6.



Case J, Class II., mitral stenosis and regurgitation and arterio-sclerosis. The figures under column A refer to the blood pressure in millimetres of mercury. The figures in column B refer to the amount of urine in ounces per diem and rate of pulse per minute. The + signs show where some of the urine has been lost and therefore the amount is under-estimated.

It will be noticed that in these cases there is a preponderance of aortic disease, though this class is not entirely limited to such cases. What is the significance of the rise of arterial pressure in this large group? Since in these observations we are taking not the mean arterial pressure but the maximum systolic pressure, it might be thought that the rise in pressure was due to the inadequacy of the aortic valves. The presence of a backward leakage through the valves will cause, if pronounced, a more rapid diastolic fall of pressure and the increased volume of blood in the dilated left ventricle will occasion an increased output of the ventricle at

The blood pressures of 18 patients were taken. Each one was made to rest for some minutes before observation reclining on a lounge chair or in bed, and several successive observations were made until the lowest possible reading was obtained with the following results: average age, 30·08 years; average blood pressure, 140·18 millimetres of mercury. As a control experiment the nurses and sisters were tested, including a somewhat anæmic subject whose abnormally high blood pressure was probably due to previous exertion, with the following result: average age, 28·8 years; average blood pressure, 129 6 millimetres of mercury. It must be noted that all these individuals pursued the same life as the patients—that is, in the open air night and day and probably had very hearty appetites. Of the patients the highest blood pressure was in the one referred to in the first instance who was progressing well and had gained 14 pounds in five weeks' treatment. It appeared to me suggestive that the examples of the highest blood pressure occurred in those patients who were clinically rapidly improving and had been under treatment the shortest time, that those who had been under treatment for a considerable time exhibited lower blood pressure, and, except for one instance, those who were not doing so well exhibited a blood pressure only a little above the normal range.

I think that these facts have a definite bearing on the question of blood pressure in relation to heart disease and I should also like to suggest that the enormous meat factor in the diet of athletes in training has had some considerable influence in multiplying the number of cases of "athletes' heart," cases which are either of an "incompetent aortic" nature or of the "dilated and hypertrophied heart" type. It would be interesting to compare the effects of severe training on the circulatory mechanism on the one hand of those training on the old type of diet and on the other hand of those who were on a "Chittenden diet."

Importance of blood pressure determination for treatment.—Whatever may be the etiology of the raised arterial tension in such cases the results I have brought forward will, I think, serve to demonstrate the great importance of a reading of arterial pressure in all cases in which we have to treat the cause of failing heart. It enables us in most cases at once to relegate the case to one of two classes. In the first class it is the heart muscle to which we have to direct the whole of our attention. If we bleed it is to relieve temporarily the distended right heart. If we give oxygen it is to improve the nutrition of the heart and to relieve it in cases of mal-oxygenation by relaxation of arterial spasm. If we give digitalis it is for its steadying and anabolic effects on the heart muscle. On the other hand, in the second class our first thought must be the reduction of the high pressure which has worn down the working power of the heart muscle. Bleeding in such cases would not only give a temporary relief to the heart. It would also, by affording a stimulus to building up of the tissue, enable the organism to apply its nitrogenous waste products to this purpose, and so tend to the purification of the circulating fluid. On the assumption that there is a plethora in the widest sense of the term and that it is primarily due to an excess of income over expenditure, the treatment which would seem to be indicated would run on the old-fashioned lines of bleeding and purging. At the same time there must be a complete reformation of mode of life. The income must be diminished by limitation of food; the output must be increased where necessary by regulated exercise. It is probably in cases such as these that Oertel's methods of treatment of heart disease have been most successful. Whether, however, limitation of fluids in the diet is desirable I am inclined to doubt. Although increased fluids tend to the perpetuation of the plethora present in these cases too rigid a restriction of fluid must seriously hinder the excretion of the hypothetic toxic substances which we have assumed to be the cause of the disorder.

These suggestions for treatment must be put forward at present only tentatively. Although I have Professor Allbutt's support in the recommendation of restriction of diet and exercise, the treatment is founded on what is at present only a hypothesis. Before this hypothesis can be established we must show that in patients, still in excellent health but with an abnormally high arterial pressure, it is possible to reduce this pressure to, say, 120 millimetres of mercury by exercise and restriction of diet without interfering with the physical well-being of the patient. Most of the cases which I have dealt with above are already too far gone for any hope of permanent alleviation and the treatment in these has had to be palliative rather than curative. By the use of nitrites it is possible to lower the pressure in some of these cases and sometimes to give some measure of relief to the heart and to the patient. In this mode of treatment, however, we are attacking the result, and not the cause, of the disease and cannot therefore expect any lasting benefits to result from our treatment.

These brief and somewhat disjointed notes have been collected at various periods during the carrying out of a general practice. They are therefore necessarily incomplete and of an amateur character, but none the less I hope that they contain matter of some interest to the profession. I must express my indebtedness in the first place to my brother, Professor Starling, for the valuable help he has given me during the preparation of this paper, especially in regard to the physiological interpretation of many of the phenomena set forth herein; in the second place to Dr. Martin for the loan of notes and papers relating to the estimations of blood pressure in various conditions; and last, but not least, to the medical staff of the Norfolk and Norwich Hospital for their kind permission to make full use of the cases under their charge in that hospital.

A STUDY OF THE STREPTOCOCCI PATHOGENIC FOR MAN.

By F. W. ANDREWES, M.D. OXON., F.R.C.P. LOND.,
PATHOLOGIST TO, AND LECTURER ON PATHOLOGY AT, ST. BARTHOLOMEW'S HOSPITAL, LONDON;

AND

T. J. HORDER, M.D. LOND., F.R.C.P. LOND.,
MEDICAL REGISTRAR AND DEMONSTRATOR OF MORBID ANATOMY AT ST. BARTHOLOMEW'S HOSPITAL, LONDON; PHYSICIAN TO THE GREAT NORTHERN CENTRAL HOSPITAL, LONDON.

(Concluded from p. 782.)

VI. GRAPHIC REPRESENTATION OF RESULTS OBTAINED BY EMPLOYING GORDON'S TESTS UPON LARGE BODIES OF STREPTOCOCCI.

WHERE a sufficient number of specimens of streptococci has been examined from any one source, or any one disease, it is possible to express the general chemical facies of the forms found by a curve based on the *percentage* frequency of a positive reaction to each of Gordon's tests, taking these in constant order. Thus, in Fig. 2, 50 per cent. of all the colonies examined produced clotting in milk, 90 per cent. gave a positive reaction with (i.e., formed acid in) saccharose, and so on. By this means, as Gordon has already shown, broad similarities and differences become apparent, and if the number of specimens upon which the curve is based is sufficiently large, minor differences in reactions are more or less effaced. We have constructed a number of such graphic representations of our results and we subjoin a few of these as examples of this mode of treatment.

These curves illustrate several important points. The curve shown in Fig. 2 contains such a preponderance of saprophytic forms that the inclusion of 20 per cent. of parasites scarcely distinguishes it from that seen in Fig. 7. We have nevertheless included it as offering the most complete general streptococcal curve available. A comparison of Figs. 3 and 7 shows the broad distinctions between the parasitic and saprophytic streptococci. The pneumococci in Fig. 4 offer a very different picture owing to the high raffinose—and relatively high inulin—percentages, while the glucosides stand at a very low level. The contrast between Figs. 5 and 6 is of special interest, as illustrating the wide distinctions between the streptococci concerned in acute suppurative processes and those found in malignant endocarditis; the latter, as we have previously urged, correspond very closely with the common saprophytes of the alimentary canal, as is seen by comparing Figs. 6 and 7. Lack of space prevents our enlarging further on these curves, which must be left to speak for themselves.

VII. THE BEARING OF THESE INVESTIGATIONS UPON DIAGNOSIS AND TREATMENT.

Accurate diagnosis in any case of streptococcal infection, Wellcome, a univalent serum for use in cases of infection by streptococcus pyogenes, in the manufacture of which some five or six strains tested by us were exclusively employed. This univalent "pyogenes serum" has already given good results in some cases, and in one, at least, where a polyvalent serum had proved less satisfactory in its effect. It is as yet too early to speak confidently of its advantages over the polyvalent sera in ordinary use. With univalent sera ready to hand against the different types of streptococci the appropriate one could be employed as soon as the organism in any particular case was isolated and tested. This would obviate the alternative course of preparing a special univalent serum *after* the separation of the organism, as carried out by one of us (T. J. H.) on two occasions in cases of malignant endocarditis.[1] This method is impracticable in all but the most chronic cases, for it involves the loss of valuable time; no serum can be expected to be rich in antibodies in less than from six to eight weeks.

The nature of the antibodies in the serum of an animal immunised against streptococci is presumably opsonic. There is no evidence that they are antitoxic or directly bactericidal. The question may properly be raised as to the precise specificity of such opsonins within the group of streptococci. Bulloch and Western, in a recent paper,[2] have demonstrated that as regards staphylococcus aureus, the tubercle bacillus, and bacillus pyocyaneus perfectly distinct opsonins are concerned. These three organisms, however, belong to distinct genera, and we know of no evidence as to the specificity of opsonins within the limits of a single genus. Lack of time has alone prevented our attacking this interesting problem amongst the streptococci. It may be that there is a single opsonin against all streptococci, but in the absence of any evidence to this effect such a presumption would be exceedingly unsafe; such collateral evidence as may be found amongst the agglutinins is against it.

A new chapter has recently been opened in the treatment of streptococcal infections by the guarded use of specially prepared vaccines (Wright). The good results which have undoubtedly attended the injection of dead cultures of staphylococci in chronic infections by these organisms will possibly also follow a similar mode of treatment in diseases of streptococcal origin. This treatment by vaccination may prove more successful than the use of antistreptococcus serum, more particularly in cases of chronic infection. Many cases of streptococcal infection are, however, of an acute and rapidly fatal character and it may well be that serum treatment will prove better adapted for such cases than vaccination. In any case it remains a matter of paramount importance that the type of streptococcus concerned in the case should be recognised. Given the ready means for recognition of the different types of streptococci, specific vaccines of known strength might be ready at hand as soon as the diagnosis has been established.

Pathological Department, St. Bartholomew's Hospital.

THORACOTOMY FOR TRAUMATIC HÆMOTHORAX DUE TO A WOUND OF AN INTERCOSTAL ARTERY.

By DONALD DUFF, F.R.C.S. EDIN., F.F.P.S. GLASG.,
SURGEON TO THE GLASGOW CENTRAL DISPENSARY; EXTRA ASSISTANT SURGEON TO THE GLASGOW ROYAL INFIRMARY, ETC.;

AND

JOHN ALLAN, L.R.C.P., L.R.C.S. EDIN., L F.P.S. GLASG.,
EXTRA SURGEON TO THE GLASGOW CENTRAL DISPENSARY.

WOUNDS of the intercostal arteries, except as part of severe injury to the chest wall, are comparatively rare, and especially so when the injury occurs to the larger or superior branch. This vessel from its anatomical position—in the groove on the lower part of the internal surface of the rib—is well protected from injury by the overlapping inferior border of that bone; stab wounds which penetrate the chest wall usually miss the vessel or at most only divide the smaller branch which runs along the lower part of the intercostal space. The following case occurring in the practice of one of us (J. A.) is of interest.

The patient, a man, aged 46 years, accidentally fell through a glass door on Dec. 22nd, 1905, and received a V-shaped wound of the chest wall in the sixth left intercostal space and distant about 1½ inches from the mid-sternal line; the apex of the V pointed downwards and inwards towards the umbilicus. The general shape of the wound beneath the skin flap was triangular, the apex being immediately below the sixth rib. There was free oozing from the depth of the wound but it was quite impossible to detect any spouting point. With antiseptic precautions a sterile probe was carefully passed, when it was found that the instrument penetrated in a slanting direction towards the lower border of the sixth rib and to a depth of four inches from the skin margin. The wound was next slightly enlarged and explored with the finger but no pieces of glass, bare rib, or definite communication with the pleural cavity could be found. The wound was carefully cleared of blood clot and packed with sterile gauze. The patient had no reactionary temperature and next day there was no stain showing through the dressings. He had passed a fair night but complained of slight pain on respiration and had a little cough. There had been no hæmoptysis. On the 24th when the wound was dressed the packing was found extruded and the skin surfaces adherent; as there was no discharge the packing was not reinserted The temperature was normal, the pulse was 84, and the respirations were 20. Friction sounds were heard in the region of the wound and from that level downwards towards the base of the lung. Vocal fremitus and resonance were not altered and the patient still complained of pain on respiration and of cough. He continued pretty much in the same condition for the next two or three days, the difference in breath sounds, on percussion, in vocal fremitus and vocal resonance not being much different in comparison with the other side. On the 28th, six days after the injury, the breathing was more difficult and the patient complained of a choking sensation. Comparative dulness was present from the level of the wound to the base of the lung, both in front and at the back, the upper line of the dulness altering with change of position. The apex impulse was displaced to within half an inch of the left sternal margin. The respiratory murmur was diminished in intensity. The respirations numbered 24 per minute, the pulse was 86 and the temperature was normal. An exploratory needle was introduced into the pleural cavity and blood-stained fluid was found, which, however, contained no pus cells and no micro-organisms. On the night of the 28th the patient when seen by one of us (D. D.) had orthopnœa and complained much of a choking feeling when asked to lie back in bed. The movements of the chest wall were free on the right side but limited on the left; comparative dulness was present over the base of the lung behind but was not so marked in front. The patient appeared to be in a serious condition and a diagnosis of hæmothorax due to a wound of the upper branch of the sixth intercostal artery was made. Operation was decided on and thoracotomy was performed as the only feasible means of securing the bleeding point and of relieving the urgent symptoms due to the intrathoracic hæmorrhage. An incision was made in the line of the original wound and the tract of the laceration was explored; the apex of the wound was found just below the sixth rib and hæmorrhage was taking place from both proximal and distal ends of the divided intercostal artery. A small opening which admitted the point of a pair of dressing forceps was found in the parietal pleura and from this opening the blood escaped from the chest at considerable pressure; this opening was enlarged, giving exit to a large quantity of blood, considerably over a pint being evacuated. The blood was allowed to escape from the chest slowly by soaking through a pad of gauze, in order to minimise as much as possible the effect of sudden relief of intrathoracic pressure The periosteum over the sixth rib was incised and stripped down with an elevator; the two ends of the divided intercostal artery were raised from the groove on the posterior surface of the rib and tied. A drainage-tube was inserted and the wound was partially stitched and packed. After the operation the respiration was much improved and the pulse was of good volume and tension. During the operation the anæsthetic (chloroform) gave some anxiety but the difficulty experienced was successfully overcome. On the 29th some serum was present on the dressings but no fresh hæmorrhage had taken place; the patient had had some sleep in snatches and viewed in the light of the facts which we have set forth above, can only be obtained by carrying the bacteriological investigation a stage beyond the mere isolation of the infecting organism. The methods available for securing a pure culture of the invading streptococcus—notably the technique of blood examination—have been so improved in recent years that no great difficulty is usually encountered in this process. The organism, once isolated, must be subjected to a full investigation on the lines already laid down, which, to be complete, should include not only Gordon's nine tests but also morphology in broth culture, capacity for growth on gelatin at 20° C., and, if possible, inoculation into a mouse as soon as may be after isolation in pure culture. As a rule it is not difficult to refer any given streptococcus to one or another of the types which we have laid down above as provisional species. After what we have said as to the frequency of intermediate forms, it is not easy to present any hard and fast diagrammatic schedule, but it may be convenient to summarise the five main types to which we have given names as follows:—

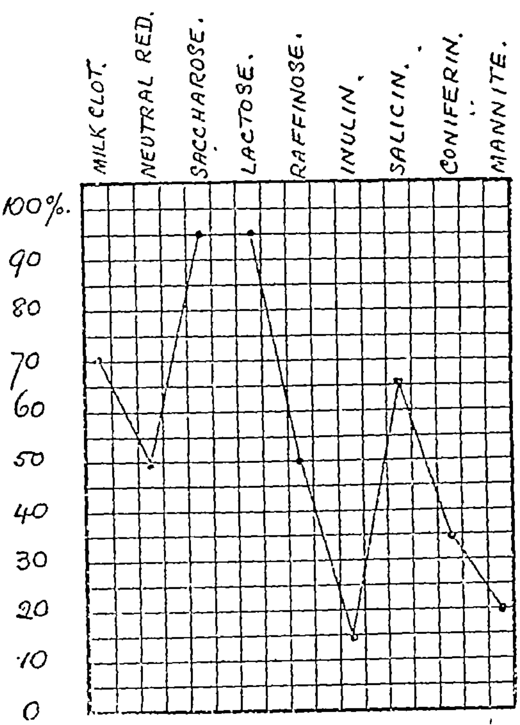
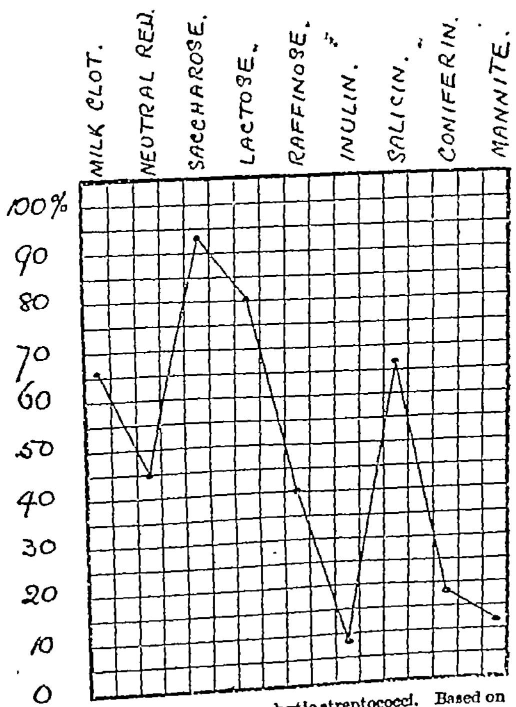
FIG. 6.



Reaction-curve of 20 strains of streptococci from cases of malignant endocarditis. Two strains of pneumococci are included.

FIG. 7.



Reaction-curve of human saprophytic streptococci. Based on 300 salivary specimens (Gordon) and 300 fæcal specimens (Houston).

NOTE.—The coniferin percentage refers to salivary sorts alone, Houston not having employed this test. It is probable that the coniferin percentage in fæcal species is higher than in salivary species, as we have found some of the most abundant fæcal forms to ferment this body.

Having ascertained the type of streptococcus concerned in any given case one is in a much better position to judge of the possible source of the organism, to form a prognosis, and to initiate treatment.

We venture to believe that the results of the investigations which we have detailed in this communication may have a very direct and important bearing upon the treatment of streptococcal infections. Already, in our preliminary remarks, we have hinted at a possible line along which serum therapy may advance with more hope of success than this treatment at present enjoys. This development consists in adapting the immune serum employed in any particular case more closely to the actual organism causing the disease. If, as we have shown, different pathogenic streptococci exhibit marked differences in their metabolic reactions *in vitro*, it is highly probable that the effects of these streptococci upon the tissues are associated with similar marked differences in chemical action. And if this be true, it follows that a more complete antagonism between the serum and the organism may be expected if the former has been derived from an animal specifically immunised against the latter. In other words, better results may *a priori* be expected from a powerful univalent serum than from a polyvalent one, even though the latter contains as one of its ingredients an antibody against the special streptococcus concerned. It must be remembered that at present the polyvalent sera on the market are polyvalent only in the sense that they have been prepared by the use of a number of strains of streptococci derived from different sources, but not necessarily presenting any differences in chemical reaction. It is probable that the bulk of the strains which have hitherto been employed in producing polyvalent sera are referable to streptococcus pyogenes, and such sera may be in effect largely univalent, however various the diseases from which the organisms have been derived. A truly polyvalent serum would be made by inoculating a horse with each of the different types of streptococci considered in the preceding sections until the animal became immune to each type. Such a serum might well be of value in urgent cases pending the isolation and testing of the invading streptococcus, which usually occupies three or four days. But the soundest method appears to us to keep a special horse for each type of streptococcus: in this way a more or less specific serum would be available for use against each type of organism and it may fairly be presumed that the specific antibodies in such sera would be more potent than when forming only one element in a polyvalent serum.

Following out the above idea we have already had prepared for us, by the courtesy of Messrs. Burroughs and from diarrhœa for 12 months and on admission his urine was found to contain an appreciable amount of albumin. From the notes of his case it would appear that after a rigor his temperature had risen to 103° F., falling to 100° after a profuse sweating. It had then remained normal for a few days but a repetition of the rigors and sweatings had occurred. A consultation was held and the man was transferred to my wards for operation. Next day an exploring syringe was inserted in practically the same position as in the former case and pus having been found a method similar to the previous one was pursued. On exposing the surface of the liver a thin flaky pus was seen welling up from around the needle which had been left *in situ*; the wound was packed with gauze whilst the pleural sac was sutured off and the liver was fixed to the deeper planes of the wound. On opening the abscess, which was done immediately, not more than one and a half ounces of unhealthy-looking pus escaped. The temperature after the first three days fell to normal and remained so throughout his convalescence, which was uneventful. He was discharged to a sick furlough looking in good health but still with a small amount of albumin in the urine.

In the first operation when the pleural sac was opened the patient's condition from threatened respiratory failure became alarming from the action of the left lung being impeded by the pressure of the pillow beneath the chest and by the pressure of the abscess and from the presence of air in the right pleural cavity. He was turned over on his back so far as was consistent with the continuation of the operation and as soon as the cavity was shut off the breathing became normal. It is difficult for me—even if the second abscess was in existence at the time of the first operation and was overlooked, though the character of the pus it contained is against the view that it was of the same nature as that of the larger collection—to account for the disconcerting symptoms which intervened so suddenly while gently syringing the wound and partially obliterated sinus. Though it has been urged that liver pus is sterile, the entrance into the peritoneal cavity of carbolic lotion and abscess débris must have inevitably produced a more or less limited peritonitis, but the symptoms of peritonism readily disappeared under treatment with enemata and sulphate of sodium. Some small perforation may have taken place on the anterior surface of the liver, resulting in a localised abscess limited by adhesions. In the second case the numerous rigors, the high temperature, the profuse sweats, and the small size of the abscess and the character of the pus seemed to suggest a possible pyæmic origin, but the wound healed rapidly and there was no interruption of the apyrexia throughout the recovery.

Limited as my experience is in the operative treatment of hepatic abscess, I submit with all deference the opinion that it is not always advisable to rely on the use of any of the various special instruments—trocars and so forth—to the exclusion of ordinary surgical procedures, for frequently those cases in which efforts have been made for their treatment by the use of such specially devised apparatus have eventually to be submitted to an excision of a portion of a rib to insure efficient drainage. In the second case in which though the abscess was close to the surface of the liver there were no diaphragmatic adhesions and in which there was unhealthy pus welling up copiously around the needle, nothing but disaster, I think, must have followed the use alone of any form of trocar and cannula. And I venture to think that such stabs in the dark, or at least into an obscurity, are out of place in those cases which, unless there are extensive and firm adhesions present, a condition of which we can never feel assured without an incision, can only be satisfactorily grappled with by one of the accepted surgical methods.

My thanks are due to Major W. G. Beyts, R.A.M.C., Civil Surgeon W. Rice, and the late Civil Surgeon J. J. O'Halloran for their valuable assistance in these two cases.

A RUSSIAN PIONEER INSTITUTION FOR DEAF-MUTES.—At the beginning of January, 1907, says the *Novoe Vremya*, it is proposed to call a pan-Russian congress of teachers and caretakers of deaf-mute children in commemoration of the introduction into Russia of the education of deaf-mutes for the first time, in the experimental school for deaf-mutes in Pavlovsk, founded 100 years ago by the Empress Marie Theodorovna.

ENDEMIC HÆMATURIA.[1]

BY PHILIP G. STOCK, M.R.C.S. ENG., L.R.C.P. LOND., D.P.H.,

LATE CAPTAIN, R.A.M.C.

THE following notes, founded on 65 cases of endemic hæmaturia which occurred amongst the troops in South Africa in 1902, are brought to notice for two reasons: (1) they throw some light on the incubation period of the disease; and (2) because a new line of treatment is suggested which offers some hope of a definite cure. Endemic hæmaturia has been observed for many years; both its frequency and the occurrence of vesical calculi were remarked on by the French surgeons during the invasion of Egypt by Napoleon, but it was not until 1851 that Bilharz discovered the bilharzia hæmatobia in Cairo. Since then it has been observed over practically the whole of the African continent, to which, with the exception of the Mauritius, it was thought to be confined; but lately cases have been reported from Arabia, Cyprus, Antigua (W.I.), India, and even in England, which would point to its having a wide geographical distribution; in Egypt it is a common disease and a fruitful cause of urinary calculi. In South Africa I have collected information which points to its being widely distributed, and cases have been traced to the Vaal, Orange, and Apis rivers, Pretoria, M'Nkandu, Newcastle, the Mooi and Klip rivers, Umzindin and Maritzburg, and streams at Middleburg, Cape Colony, and in the Transvaal, whilst in the Rustenburg valley it is truly endemic.

The bilharzia hæmatobia is a trematode worm in which the male and female reproductive organs occur in separate individuals. The male worm is of a whitish colour and measures about 16 millimetres in length; the female is about 20 millimetres long and lies in the gynæcophoric canal of the male with her ends protruding; the eggs, which it is stated can be distinguished in the uterus, appear in the patient's urine as bright, translucent oval bodies, with a smooth surface and a thin non-operculated shell, possessing a spine situated at one end. It is stated in the text-books that this spine is sometimes situated laterally, this being especially the case when the disease involves the rectum, and the ingenious idea has been advanced that this is due to the greater pressure exercised by the fæces as compared with the urine, but in the many fresh specimens I have examined I have failed to find an ovum with a spine situated laterally.

According to Professor Looss the lateral spine is caused by the egg not being able to take up its normal position in the oötype but whilst, as mentioned before, I have never discovered this lateral placement in fresh specimens, in those which have been mounted a shrinkage may ensue giving a false impression as to the true position of the spine. The ovum contains a ciliated embryo which can be hatched out by mixing some of the urine containing it with water, when it soon acquires a rapid movement, often changing its form. Should the embryos become hatched out in the urine they quickly die and even in water they quickly disappear; the longest period that they have been kept alive is about 36 hours. Sonsino, however, states that they penetrate the body of some species of mollusc which, becoming transformed into a nurse (or redia), produces in its interior a generation of larvæ which in their turn escape and enter the body of the definite host to become mature worms.

I have endeavoured to repeat the observations of Sonsino, but so far without success, and this portion of its life-history cannot be definitely settled; it seems more likely that the embryo itself enters the human host, there to develop into the young worm. That it gains access to its human host or to the monkey, in which it has been found, by means of drinking water is, I think, borne out by the following facts. 1. An epidemic occurred amongst the men of the 8th Hussars stationed at Pretoria in 1902. The camp was situated on the hills to the north-west of the town and it was the custom of the men to bathe in the spruit (Skinner's spruit) which ran along the bottom of the camp. 43 cases occurred and in all a history of having either drunk the water or bathed in the spruit was obtained. 2. Whilst monkeys undoubtedly drink, it is improbable that they ever bathe.

---

[1] Summary of a paper read before the Transvaal Medical Society, Johannesburg.

complained much of thirst. The pulse was 90 per minute, of good volume and tension. The respirations were 18 and the temperature was 100° F. On the 30th the patient was fairly well, having slept fully nine hours. There was no stain on the dressings. The temperature was 101°, the pulse was 96, and the respirations were 24. On the next day (Dec. 31st) the wound was dressed and the drainage-tube was removed, some sterilised gauze being inserted in its place. Examination of the chest showed the presence of pneumothorax with considerable displacement of thoracic viscera; the apex impulse was half an inch to the right of the sternum and the whole left side of the chest was hyper-resonant. On Jan. 2nd, 1906, the patient was not so well, the temperature registering 100·5°, the respirations numbering 30, and the pulse being 120, but it was found that he had been taking oranges and he complained of pain in the epigastrium. He was given castor oil and on the following day he felt much better. He complained of palpitation and some friction was heard in the region of the wound. For the next few days the patient rapidly improved, the temperature fell to normal, the breath sounds became audible over the lower part of the left chest, and the apex gradually resumed its normal position. Breathing exercises were given by means of a Wolff's bottle. The wound was quite healed on Jan. 13th, a fortnight after the operation, no pus being present from first to last. The patient went out against directions and got a chill which kept him in bed for a few days, but he was practically well at the end of January and able to undertake a journey from Glasgow to Portsmouth, subsequent reports of his condition being satisfactory. At the time that he left the measurements of the chest showed a difference of three-quarters of an inch between the right and left sides at the level of the sixth rib. The temperature was normal and the respirations numbered 18. The patient felt no pain. The breath sounds were heard all over the chest on the left side but were, if anything, somewhat fainter than on the right side.

One or two points in connexion with this case are worthy of note and are, in our opinion, of sufficient interest to warrant the case being recorded. The rarity of the injury and the fact that hæmorrhage took place into the pleural cavity without any pneumothorax being present till after the chest had been opened into surgically are important features. There was undoubtedly an opening in the parietal pleura from the first produced by a pointed fragment of glass, but the wound passed in such a direction—i.e., piercing first the external intercostal muscle, then between the muscles, and then passing through the internal muscle about one inch farther back—that the overlapping tissues evidently acted like a valve and prevented the entrance of air, as they also did the exit of blood in an outward direction from the divided artery. Fortunately for the patient, although the operation was performed at his home, the aseptic precautions proved effectual and no pus was seen. Had empyema developed his chances of recovery would have been remote considering his general condition from loss of blood and shock. During the first two or three days after the operation the patient's danger appeared to arise mainly from a tendency to syncope due to the displacement and consequent embarrassment of the heart. When absorption of the air began he rapidly improved.

Glasgow.

TWO CASES OF HEPATIC ABSCESS TREATED BY THE TRANSPLEURAL OPERATION.

BY H. TAYLOR, M.A. CANTAB., F.R.C.S. EDIN., M.A., M.D. DUB.,
SURGEON-CAPTAIN, ARMY MEDICAL RESERVE.

I HAVE ventured to publish these two cases because they would seem to belong to that category in which Jacobson[1] includes "those grave and difficult cases where a hydatid cyst or hepatic abscess instead of making its way towards the abdominal wall works upwards, thrusting up the base of the lung" and so have to be approached by a transthoracic incision.

CASE 1.—A man, aged 21 years, of the 4th Battalion Manchester Regiment, was transferred from Northampton to Colchester Station Hospital for the purpose of being invalided from the service. He was, however, admitted to my wards for observation, the history of the case being that he had suffered from dysentery with an "enlarged liver" while in Ladysmith during the siege. His face was sallow and his features were somewhat "drawn" and he had a moderate diarrhœa with dark-coloured offensive pultaceous stools but with no pus or blood. There was no definite swelling to be defined, but there were a sensation of increased resistance on palpation below the costal margin and some dulness at the base of the right lung. There was no history of syphilis or malaria, the spleen could not be felt, and there were no rigors or sweatings. As there was no urgency in his symptoms and as the liver had been explored with a negative result before his transfer to Colchester, it was decided after a consultation to await more definite indications for treatment. The diarrhœa was easily controlled by a little opium, salol, and bismuth and the patient's temperature rose to 100° F. on two occasions only. On Oct. 29th, some three weeks after admission, however, the man complained of considerable pain and his temperature was found to be 102°. On the next morning, therefore, after preparations had been made for operation if necessary, the liver was again explored and after two or three attempts a cavity containing typical liver pus was entered at a depth of some three inches, the needle being between the eighth and ninth ribs, approximating to the post-axillary line. The abscess appeared to be one of those which instead of working downwards and outwards to the parietes was extending upwards and backwards to the hinder part of the liver. I therefore determined to adopt the transthoracic route in preference to the ordinary subcostal transperitoneal or subpleural intercostal incisions. The needle being left in as a guide and chloroform having been administered, an incision some three or four inches long was made over the ninth rib and about two and a half inches of it were excised, the pleura and diaphragm were cut through, and the liver was exposed. A strong suture was passed deeply through the liver substance and through the diaphragm and integuments at each end of the incision, thus anchoring the viscus securely to the wound, and the pleural cavity was then sutured off as quickly as possible. Very shallow and interrupted respiration supervened on the admission of air to the pleural sac and the patient became very cyanotic, but he rapidly recovered as soon as the cavity was securely sealed. The liver and the edges of the diaphragm were fixed by some further sutures to the deeper layers of the wound, a dressing was applied, and the patient was sent back to the ward, as it was decided to wait for a day or two to allow adhesions to form before proceeding to open the abscess. This was done on the third day after the operation and about two and a half pints of chocolate-coloured pus having been evacuated the cavity was gently syringed out with iodine water. The discharge gradually ceased and on Dec. 7th the cavity had so contracted down that a tube barely one and a half inches long was with difficulty retained in the wound. On the morning of Dec. 8th the temperature, hitherto normal since the opening of the abscess, was found to be 99·6°. While the wound was being gently syringed out with 1 in 40 carbolic lotion the patient suddenly complained of great pain in the epigastrium, became pallid, broke out into a profuse perspiration, and vomited. I was considerably alarmed, fearing that the syringing—gentle as it had been—had broken through some attenuated portion of the wall of the abscess cavity and possibly infected the peritoneum. A quarter of a grain of morphine was injected and by the evening the pain had abated and the vomiting had ceased, but the abdomen, though soft and moving easily on respiration, was somewhat distended. The temperature continued to fluctuate between 99° and 102° and a suspicion arose that there was a collection of pus in front, either intrahepatic or between the liver and the parietes, and on the 22nd a definite area of dulness being defined an incision was made just below the costal margin and a pint of creamy inodorous pus was evacuated. The temperature fell to normal that evening and the patient made a good and uninterrupted recovery.

CASE 2.—A man belonging to the 5th Royal Irish Lancers was admitted to one of the medical wards in Colchester Hospital on Oct. 7th, 1902. He had had dysentery at Ladysmith and had been operated on at Nauwport for abscess of the liver and a quart of pus was evacuated. He was invalided home and was subsequently admitted to hospital on the above date. He had suffered more or less continuously have all been suggested as possible causes. Sir Patrick Manson gives as his own theory the continual wounding of the little toe, the most exposed portion of the foot, by the sharp grasses and jungle through which the sufferers from this disease are accustomed to walk barefooted. In the case reported above there was no history of loin pains, of any other persons of the family having suffered from this disease or from leprosy, or of the patient having at any time worn toe-rings. He had gone barefooted up to the time when he had left home but there was no jungle and very little grass at Port Antonio.

THE STUDY OF A CASE OF PLAGUE.

By J. BURTON CLELAND, M.D., CH.M. SYDNEY,
GOVERNMENT PATHOLOGIST AND BACTERIOLOGIST, PERTH, WESTERN AUSTRALIA.

(From the Pathological Laboratory, Department of Public Health, Perth.)

IN a community almost entirely of European descent and where the incidence of plague is slight those cases that do occur offer exceptional facilities for studying its etiology, spread, and symptoms. In one of the recent cases in Perth, Western Australia, the date of onset of the symptoms seemed to suggest that these were coincident with the death of a proportion of the bacilli and the consequent liberation of an endocellular toxin. As this, if true, may throw some light on the lengthy incubation periods of various infectious diseases the circumstances seem worthy of record.

The patient, a young man, worked as a painter in the "infected area" (that is, the area in which infected rats were known to be present) in Perth but resided in a healthy suburb. About ten days before becoming ill he had noticed the smell of dead rats in the workshop, but the infection probably dated from some days later. He had some diarrhœa from May 9th to 12th but only became ill on the morning of the 13th, when he had "shivers" and his temperature rose to 104° F. Next day he had severe pain in the left groin and the case was reported as plague to the Central Board of Health in the evening of that day; his temperature was then 102·6° and the pulse was 90. On examination on the morning of the 15th the temperature was 101·4° and the pulse was 102 and soft. The eyes had a salmon coloured suffusion (very characteristic of cases of plague in Australia), the tongue being thickly coated and dry. He was very restless and complained of a frequent desire to pass urine and stools, as well as of pain in the left lower part of the abdomen and both groins. There were diffuse firmness and tenderness over the left iliac region and in the left groin; these were less marked in the right groin. No glands were definitely palpable. There were no sores on the legs. The matron at the Plague Hospital said the patient had the "plague smell."

A hypodermic needle was inserted into the left groin and one drop of a sero-sanguinolent fluid was withdrawn. This contained enormous numbers of plague bacilli, some of which were bipolar but many had a degenerated appearance. In blood films made at the same time the plague bacilli, typically bipolar, were two or three times as numerous as the leucocytes, say, roughly, 15,000 per cubic millimetre. Pure cultures were obtained from these two sources. The patient became rapidly worse and died suddenly in a "kind of convulsion" about 6 P.M.

Necropsy.—At the post-mortem examination (15 hours after death) there were found on the chest from 15 to 20 small red papules with yellow centres, usually connected with hairs; there were scattered similar ones on the thighs. There was a purplish area of about the size of half-a-crown where the needle had been inserted in the groin. On opening the abdomen a little yellowish bloody fluid escaped. The whole of the retro-peritoneal tissues from the lower part of the liver into the pelvis were the seat of a hæmorrhagic exudation and quite black. This condition extended on to the anterior abdominal wall nearly as far as the umbilicus and into the iliac regions, ending as streaks and splashes of hæmorrhage. The various imbedded glands were enlarged but not markedly so. This hæmorrhagic condition extended behind Poupart's ligament into both groins, where it was very extensive; in the left groin there was in addition a solid gelatinous-looking œdema. The liver was large, pale, and glistening with a few petechiæ: the spleen was large and rather firm; the kidneys were engorged, large, with numerous large petechiæ on the surface; the suprarenals were healthy. The intestines seemed normal save for various splashes of blood under the serous coat of the descending colon, sigmoid flexure, and rectum. The bladder showed similar subserous hæmorrhages. The mesenteric glands were neither enlarged nor hæmorrhagic. There were scattered petechial hæmorrhages in the mesentery. The lungs were normal, with a very few petechiæ. There were a few subpericardial petechiæ; the blood in the heart was partly fluid, partly tarry. A film from the spleen showed great numbers of typical bipolar bacilli. In a film from the bloody exudate of the thigh several plague bacilli were seen in each field, but they were small, diplococcal-looking, and often in chains of several elements.

Relation of onset of symptoms to death of bacilli.—As has been already stated, the film made from fluid taken from the bubo during life contained inconceivable numbers of plague bacilli but comparatively few of these were typically bipolar, the great majority appearing as granular, irregular, and broken-up fragments. In marked contradistinction to this appearance were the pictures presented by blood films taken at the same time and films from the spleen obtained post mortem, in both of which the plague bacilli were beautifully bipolar. As the patient had only been ill for 48 hours before the taking of the film from the groin it seemed barely possible that the plague bacilli had multiplied there to such an extent (the film was nearly "black" with them) and then had died to such an extent, all within that brief period. The interpretation, in fact, which naturally suggested itself for this case and plague in general was this—that living plague bacilli probably liberate no toxic bodies or very few; dead bacilli, as we know, from the reaction to protective inoculation, set free powerful ones. If living plague bacilli gain entrance through the skin of the lower limb they would reach, by means of the lymphatics, the glands in the groin, they would here multiply and, in certain instances, escape onwards, finally, in septicæmic cases, reaching the blood. Being still alive there would, so far, be no reaction in the tissues and the patient would still be in the incubation period of the disease. Eventually, however, the bacilli, as the result of anti-microbic bodies or the exhaustion of food supply or for other reasons, die and, as would be expected, die first where they have had longest residence. As they die their endocellular toxins are liberated and local and systemic reaction follow in proportion to the dose. As it is only in rare instances that the bacilli remain and multiply at the point of inoculation or in the lymphatic vessels leading to the nearest glands lymphangitis seldom appears. It is otherwise in the lymph glands themselves in which multiplication has been marked and with their death we find the rapid formation of a bubo indicative of the local reaction to the liberated toxin and the first systemic symptoms of the disease due to its generalised effect. As antitoxins are now rapidly formed in response to the presence of these toxic bodies, the increasing doses of poison set free by the death of the bacilli in other parts are combated to a greater or less extent by them. Hence further buboes are rare, though they may occur, even up to a late date, given the rapid death of many bacilli in any particular local area and a low content of antitoxin at that spot.

Perhaps the best way to test the view here propounded is to see how its acceptance agrees with facts and explains away difficulties. Thus:—

1. If plague is, as a rule, due to inoculation through the skin, *why is there so seldom any local reaction and as rarely a lymphangitis*, these being such marked features of a wound infection by, say, streptococci? Because living plague bacilli exert only a mechanical effect and not a toxic one on the tissues, and as they only rarely remain and multiply at the seat of inoculation (such as an insect bite) or in the lymphatic vessels, no reaction follows. Hunter,[1] in THE LANCET, describes a case in which the inoculated area was comparatively large (a scratch): in which in consequence the bacilli remained and multiplied, as they did in the lymphatics also, and in which, but not until the third day, signs of reaction appeared. But if the signs of inflammation were not due to the death of the bacilli but to the presence of the living ones why was the inflammation

---

3. Even when bathing a certain amount of water generally enters the mouth and nose and is swallowed. 4. The disease having occurred in men who had only drunk the water, the view that the parasite enters the body by creeping up the urethra or anus is, I think, hardly admissible and there is no other known example of an entozoon introducing itself except by the mouth. 5. Only a small percentage of the patients with the disease who have come under my observation suffered from veldt sores, disproving the theory advanced that the embryo gains access through such an abrasion.

The parasite having entered the human host makes its way to the portal system, where the worm can be found in the smaller veins; the prostatic plexus and veins of the bladder wall are a favourite site. The time which elapses between its entrance and the onset of symptoms, which we may call the incubation period, seems to be settled from the observations of Dr. Abercrombie, who was in medical charge of the 8th Hussars during the epidemic previously referred to and who kindly provided me with the following notes. During the time that the regiment was at Pretoria several young drafts were sent out direct from England and all in due course bathed in the spruit and as a result several cases occurred in young soldiers whose residence in the country had not been more than two months. The shortest period observed was one month and the longest two months; thus it is concluded that the average incubation period is about six weeks.

On the symptoms of the disease it is not proposed to dwell at length; the hæmaturia probably first calls the patient's attention to his condition, although even then he does not always seek advice, as Dr. Abercrombie knew of many men in the regiment who were performing their mounted duties and had never reported sick, yet were passing large quantities of blood. The complications are due to the mechanical blocking of the vessels or the irritation set up by the ova. The worm living in the vein discharges its eggs which work their way through the tissues into the bladder or rectum, as the case may be. Perhaps the most characteristic lesion is seen in the interior of the bladder, where rounded, projecting masses with a rough and granulated surface are found, the result of inflammatory processes set up by the deposit of eggs in the mucous and submucous tissues. The uterus may also be affected and in one case the patient developed epididymitis which could only be ascribed to a similar cause. The large intestine is a common seat and the bleeding, taken in conjunction with the polypoid growth, may lead to an erroneous diagnosis of piles unless a microscopical examination be made. The ova have been found in the liver and lungs, in which latter they may give rise to hæmoptysis, but are not usually in sufficient numbers to cause symptoms.

An examination of the blood in this disease shows that the number of eosinophiles is enormously increased—20 per cent. or higher. In ten cases in which I made a differential count they ranged from 6 to 20 per cent. This increase in eosinophiles is not peculiar to bilharzia but often occurs in all worm parasitic diseases; in trichinosis it may actually amount to 68 per cent. of a leucocytosis of 20,000. What its exact significance or cause is is doubtful; possibly it is due to the action of some toxin or secretion of the worm circulating in the plasma. In my experience the increase is less marked in cases which have persisted for some months. Another interesting point, not usually mentioned, is the presence of fat in the urine—the quantity is best estimated by Shoxolite's process; the largest amount found was 2 per cent, and at first it was thought that this bore a definite relationship to the increase of the eosinophiles but further observation did not bear out this view.

The question of treatment has now to be considered. Up to the present the treatment has been simply symptomatic, as any drugs that will kill the parent worm must necessarily destroy the host. Prolonged inhalation of chloroform or ether, extending over many hours, has been suggested, but to me seems hardly feasible; perhaps the best results have been obtained with methylene blue. Change of climate is often advised, but what is far more important is to prevent the risk of re-infection by only drinking boiled water, or water known to be pure, and the avoidance of bathing in infected streams. It has been suggested by Colonel Birt, R.A.M.C., that the use of a "toxin" in these cases should produce good results and this is borne out by the following facts. Two patients who were suffering from bilharzia contracted enteric fever and on convalescing the urine was found to be free from the ova, and during the time they were under observation (some months) they had no recurrence of symptoms. At the post-mortem examination which was held on a native who died from dysentery and in which the bilharzia parasites were dissected out within two hours of death, the worms were found to be dead; there were well-marked dysenteric lesions of the intestines. The ascaris lumbricoides is almost invariably killed by acute infections. This seems to offer some hope of success in what must be either an incurable disease or one in which time is the only remedy.

The toxin might be conveniently administered by the hypodermic injection of Wright's antityphoid serum. It would not be necessary to give sufficiently large doses to produce a serum reaction, but a series of small doses might be tried which would cause little or no inconvenience. I have at any rate to suggest this treatment for your favourable consideration, as in severe cases the patients will gladly welcome any treatment which offers any hope of success. I have two patients undergoing this treatment, the result of which I hope to publish later. The question arises whether patients returning to England with the disease would be capable of spreading infection, but until Sonsino's observations have been confirmed and it has been shown that the mollusc or other intermediate host, or even the embryo itself, can live in the cold streams at home, it is a question that must remain unsettled, the general opinion being that there is no such risk.

A CASE OF AINHUM.

BY D. MOORE ALEXANDER, M.D. VICT.,
ALEXANDER FELLOW IN PATHOLOGY, THE UNIVERSITY OF LIVERPOOL;
AND
ROBERT DONALDSON, M.A., M B., CH.B. EDIN.,
LATE SENIOR HOUSE SURGEON, ROYAL SOUTHERN HOSPITAL, LIVERPOOL.

THIS rare local disease occurred in a seaman, aged 44 years. He was a native of Jamaica and had been born in Port Antonio where he had spent his youth until he was 14 years old, at which age he had left home and gone to sea. When he would be about 24 years of age a slight excrescence appeared on the inner side of the flexor aspect of the minimus of the right foot in the flexure of the distal inter-phalangeal joint. This the patient treated as a corn and pared it down. It slowly grew again and the paring process had to be repeated. The growth was, however, exceedingly slow, so that months elapsed between the use of the knife. On making an examination of the feet, the little toe looked as though a hair or some fine ligature had been drawn tightly round the distal joint and had eaten its way into the flesh. This effect was heightened by the fact that the part beyond the constriction was much hypertrophied, being as large as a hazel-nut and lay doubled up underneath the proximal portion of the toe. The bridge of tissue connecting these parts together was very narrow. There were a slight amount of excoriation and ulceration at the flexure. The toe was freely moveable upon the bridge of tissue but rather painful. The hypertrophied portion felt tense to the touch. The man complained of the pain, which made walking uncomfortable, and asked to have the part beyond the constriction removed. This was done with a sharp pair of scissors and the hard fibrous tissue that composed the band of constriction did not bleed at all in the process. The other toes of both feet were carefully examined but no traces of any constriction were found.

The literature on the subject of this uncommon disease is not large; the only account of any length is to be found in Sir Patrick Manson's "Tropical Diseases." The description given there of the early stages agrees very closely with the foregoing account of this case. It appears to attack only the dark-skinned races and to begin usually with the little toe. It is rare in women and children and most common in adult males. There is nothing noteworthy in the pathology beyond hypertrophy of the adipose tissue which infiltrates the bone in the part beyond the constriction. The theories as to the true nature and cause of this disease are numerous. That it may be a trophic nervous disturbance is supported by the occurrence in some cases of severe loin pains in the earlier stages and by the hereditary tendency noticed by some observers. Leprosy, scleroderma, the wearing of toe-rings have all been suggested as possible causes. Sir Patrick Manson gives as his own theory the continual wounding of the little toe, the most exposed portion of the foot, by the sharp grasses and jungle through which the sufferers from this disease are accustomed to walk barefooted. In the case reported above there was no history of loin pains, of any other persons of the family having suffered from this disease or from leprosy, or of the patient having at any time worn toe-rings. He had gone barefooted up to the time when he had left home but there was no jungle and very little grass at Port Antonio.

Liverpool.

THE STUDY OF A CASE OF PLAGUE.

BY J. BURTON CLELAND, M.D., CH.M. SYDNEY,
GOVERNMENT PATHOLOGIST AND BACTERIOLOGIST, PERTH, WESTERN AUSTRALIA.

(From the Pathological Laboratory, Department of Public Health, Perth.)

IN a community almost entirely of European descent and where the incidence of plague is slight those cases that do occur offer exceptional facilities for studying its etiology, spread, and symptoms. In one of the recent cases in Perth, Western Australia, the date of onset of the symptoms seemed to suggest that these were coincident with the death of a proportion of the bacilli and the consequent liberation of an endocellular toxin. As this, if true, may throw some light on the lengthy incubation periods of various infectious diseases the circumstances seem worthy of record.

The patient, a young man, worked as a painter in the "infected area" (that is, the area in which infected rats were known to be present) in Perth but resided in a healthy suburb. About ten days before becoming ill he had noticed the smell of dead rats in the workshop, but the infection probably dated from some days later. He had some diarrhœa from May 9th to 12th but only became ill on the morning of the 13th, when he had "shivers" and his temperature rose to 104° F. Next day he had severe pain in the left groin and the case was reported as plague to the Central Board of Health in the evening of that day; his temperature was then 102·6° and the pulse was 90. On examination on the morning of the 15th the temperature was 101·4° and the pulse was 102 and soft. The eyes had a salmon coloured suffusion (very characteristic of cases of plague in Australia), the tongue being thickly coated and dry. He was very restless and complained of a frequent desire to pass urine and stools, as well as of pain in the left lower part of the abdomen and both groins. There were diffuse firmness and tenderness over the left iliac region and in the left groin; these were less marked in the right groin. No glands were definitely palpable. There were no sores on the legs. The matron at the Plague Hospital said the patient had the "plague smell."

A hypodermic needle was inserted into the left groin and one drop of a sero-sanguinolent fluid was withdrawn. This contained enormous numbers of plague bacilli, some of which were bipolar but many had a degenerated appearance. In blood films made at the same time the plague bacilli, typically bipolar, were two or three times as numerous as the leucocytes, say, roughly, 15,000 per cubic millimetre. Pure cultures were obtained from these two sources. The patient became rapidly worse and died suddenly in a "kind of convulsion" about 6 P.M.

Necropsy.—At the post-mortem examination (15 hours after death) there were found on the chest from 15 to 20 small red papules with yellow centres, usually connected with hairs; there were scattered similar ones on the thighs. There was a purplish area of about the size of half-a-crown where the needle had been inserted in the groin. On opening the abdomen a little yellowish bloody fluid escaped. The whole of the retro-peritoneal tissues from the lower part of the liver into the pelvis were the seat of a hæmorrhagic exudation and quite black. This condition extended on to the anterior abdominal wall nearly as far as the umbilicus and into the iliac regions, ending as streaks and splashes of hæmorrhage. The various imbedded glands were enlarged but not markedly so. This hæmorrhagic condition extended behind Poupart's ligament into both groins, where it was very extensive; in the left groin there was in addition a solid gelatinous-looking œdema. The liver was large, pale, and glistening with a few petechiæ; the spleen was large and rather firm; the kidneys were engorged, large, with numerous large petechiæ on the surface; the suprarenals were healthy. The intestines seemed normal save for various splashes of blood under the serous coat of the descending colon, sigmoid flexure, and rectum. The bladder showed similar subserous hæmorrhages. The mesenteric glands were neither enlarged nor hæmorrhagic. There were scattered petechial hæmorrhages in the mesentery. The lungs were normal, with a very few petechiæ. There were a few subpericardial petechiæ; the blood in the heart was partly fluid, partly tarry. A film from the spleen showed great numbers of typical bipolar bacilli. In a film from the bloody exudate of the thigh several plague bacilli were seen in each field, but they were small, diplococcal-looking, and often in chains of several elements.

Relation of onset of symptoms to death of bacilli.—As has been already stated, the film made from fluid taken from the bubo during life contained inconceivable numbers of plague bacilli but comparatively few of these were typically bipolar, the great majority appearing as granular, irregular, and broken-up fragments. In marked contradistinction to this appearance were the pictures presented by blood films taken at the same time and films from the spleen obtained post mortem, in both of which the plague bacilli were beautifully bipolar. As the patient had only been ill for 48 hours before the taking of the film from the groin it seemed barely possible that the plague bacilli had multiplied there to such an extent (the film was nearly "black" with them) and then had died to such an extent, all within that brief period. The interpretation, in fact, which naturally suggested itself for this case and plague in general was this—that living plague bacilli probably liberate no toxic bodies or very few; dead bacilli, as we know, from the reaction to protective inoculation, set free powerful ones. If living plague bacilli gain entrance through the skin of the lower limb they would reach, by means of the lymphatics, the glands in the groin, they would here multiply and, in certain instances, escape onwards, finally, in septicæmic cases, reaching the blood. Being still alive there would, so far, be no reaction in the tissues and the patient would still be in the incubation period of the disease. Eventually, however, the bacilli, as the result of anti-microbic bodies or the exhaustion of food supply or for other reasons, die and, as would be expected, die first where they have had longest residence. As they die their endocellular toxins are liberated and local and systemic reaction follow in proportion to the dose. As it is only in rare instances that the bacilli remain and multiply at the point of inoculation or in the lymphatic vessels leading to the nearest glands lymphangitis seldom appears. It is otherwise in the lymph glands themselves in which multiplication has been marked and with their death we find the rapid formation of a bubo indicative of the local reaction to the liberated toxin and the first systemic symptoms of the disease due to its generalised effect. As antitoxins are now rapidly formed in response to the presence of these toxic bodies, the increasing doses of poison set free by the death of the bacilli in other parts are combated to a greater or less extent by them. Hence further buboes are rare, though they may occur, even up to a late date, given the rapid death of many bacilli in any particular local area and a low content of antitoxin at that spot.

Perhaps the best way to test the view here propounded is to see how its acceptance agrees with facts and explains away difficulties. Thus:—

1. If plague is, as a rule, due to inoculation through the skin, *why is there so seldom any local reaction and as rarely a lymphangitis*, these being such marked features of a wound infection by, say, streptococci? Because living plague bacilli exert only a mechanical effect and not a toxic one on the tissues, and as they only rarely remain and multiply at the seat of inoculation (such as an insect bite) or in the lymphatic vessels, no reaction follows. Hunter,[1] in THE LANCET, describes a case in which the inoculated area was comparatively large (a scratch); in which in consequence the bacilli remained and multiplied, as they did in the lymphatics also, and in which, but not until the third day, signs of reaction appeared. But if the signs of inflammation were not due to the death of the bacilli but to the presence of the living ones why was the inflammation

---

[1] THE LANCET, July 14th, 1906, p. 83.

postponed till the third day, when we know that a streptococcal wound infection may show the first signs of reaction in as early a time as six hours? Further, the minuteness and the nature of the wound caused by a suctorial insect (such as a flea) probably both aid in enabling the bacilli to pass on without multiplying locally.

2. *Why is one set of glands, and most usually those of the groin, alone affected?*—Because these are the glands draining the area of inoculation; in them the bacilli are first arrested and multiply greatly before passing on to other groups or the blood stream. In them they die first and in greatest numbers and in consequence set up an intense local reaction—the bubo.

3. *Why are buboes sometimes absent?*—Because the bacilli have entered the body by other routes than skin inoculation; or, if the latter has occurred, they have escaped the nearest glands by entering more directly into the blood stream or have multiplied in the glands to a less extent than usual.

4 *Why do buboes sometimes appear as late as the second week of the disease?*—This has been already explained.

5. *Why do no symptoms appear during the incubation period* of this disease (and probably some other diseases), though we know that during this period the bacteria are multiplying rapidly and must be present in great numbers? Because the living bacilli are not toxic and it takes some days before anti-microbic bodies or other forces can destroy a sufficient number of the bacilli and so set free large doses of toxin.

It will be seen that this view, if adopted, lends strong support to the skin inoculation theory of plague, so ably set forth and supported by Dr. J. Ashburton Thompson of Sydney in his "Plague Reports," and which our experience here gives us strong grounds for supposing to be correct. To conclude, the theory I have set forth may be summed up in an apparent paradox: The onset of signs and symptoms in plague is the first indication of commencing recovery from the disease!

Perth, Western Australia.

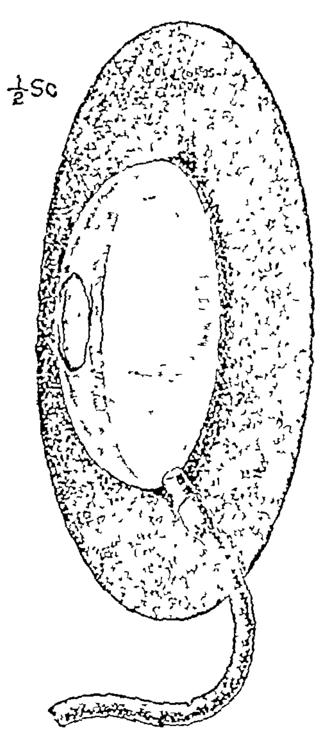
THE SUPRAPUBIC DRESSING.

BY G. H. COLT, M.A., M.B. CANTAB., M.R.C.S. ENG.

IN THE LANCET of Nov. 4th, 1905 (p. 1322), there is an account of some experiments which led up to a device described as a new dressing for cases of suprapubic cystotomy. The selection of the size of the apparatus was necessarily a matter which needed more extended observation and as a result of this it has been found necessary to add to the set of apparatus the two pieces described below. The oval glass has been produced by Messrs. Down Bros., Limited, only after very considerable trouble and expense. Whereas the cylindrical pattern can be readily made by a glass blower from glass tubing the oval pattern has to be manufactured by means of a mould. It is unnecessary to enter into a description of the various experimental patterns which were made to determine the size and shape of the oval. The final steel mould was made as a sequence to these experiments and the oval glass as now turned out from it is very satisfactory. The accompanying illustration shows the pattern to half scale but it is difficult to show in a drawing the many small points material to the actual apparatus.

The chief points are the following. 1. The sides bulge out in a regular manner all along the circumference of the oval, so that the rubber fits the glass evenly and closely and there is no leakage of urine or lotion between the two. 2 A groove is provided so that the rubber can be tied on to the glass. This is unnecessary in the case of the cylindrical vessel, but in the oval pattern leakage is liable to occur unless the rubber is fastened in some way. 3 All the edges are rounded off and the base is also machined up flat so as to avoid the risk of ulceration from unequal pressure. The oval pattern is large enough to cover the very largest wound that is likely to be made and it can be applied so soon as the urine is free from blood clot, that is to say, on the second or third day after the operation. The method of its application is precisely as described in the former paper, and is now well known. The chief essential detail is to shave the skin very close. It is often noticed that the edge of the rubber disc curls up in places after it has been applied. As a rule it uncurls again of its own accord and becomes fixed to the skin. This curling up does not occur when the solution is used in small quantity and is well rubbed in, but it sometimes happens that this is impossible.

The second addition to the set of the apparatus is the provision of two separate oval pieces of sheet rubber, each measuring six inches by four inches, and having punched out in the long axis of the oval, but half an inch eccentrically, a hole of the size required for the large or the small cylindrical glass. A pendulous abdomen interferes with the application of the oval glass by reason of its size and it is far more satisfactory in these cases not to increase but to diminish the size of the *rigid* part of the dressing and to increase at the same time and to the same extent the *flexible* part—namely, the rubber. This at once solves the problem and as the rubber adapts itself excellently to all folds and wrinkles the small glass remains suspended over the wound and is efficient. A very large wound can be dressed in this way, and since the troubles of nursing these patients by the old method varied directly with the weight of the patient and the size of the abdominal wall, the latter when large being frequently coincident with a pendulous abdomen and a gaping wound, the utility of this simple addition is evident.



Suprapubic dressing, oval pattern.

In case it should be desirable for the patient to get up while he is wearing the oval glass this is also made up as a separate piece with the dome solid except for a pin-hole opening remote from the exit-tube. The risk of urine overflowing as the patient moves about is thus minimised. These cases are not common as a matter of experience, though one would expect them to be so since prostatectomy is common and the patients are generally over 50 years of age and liable to bronchitis. It is unnecessary, therefore, to enter on this part of the subject at greater length here. If the small cylindrical glass is used for this purpose the variety with a side tube in place of the hole at the top is employed so that the margin of safety from overflow may remain the same. The selection of the piece best suited to the case is a matter which anyone who understands the principles involved can make for himself without much difficulty.

There is no doubt that the dressing can be both used and abused. For instance, it is not uncommon to see the wound inside the glass remaining uncared for. Several such wounds have closed while the glass has been in place but it is probable that they would have closed sooner if they had been attended to regularly, say once a day, by means of a pair of sinus forceps or with a probe passed through the upper opening of the dressing. The caustic probe is particularly useful in this respect and is much more handy and efficient than a stick of caustic. Moreover, the ease with which the caustic can be renewed by redipping the probe in fused silver nitrate which is on the point of solidifying results in a great saving of caustic. Apart from this lack of attention to the wounds their condition is precisely what it was when they were ressed with gauze and on drying and inspecting them no fference between the two can be discovered. Then, again, e discs of rubber with the holes properly punched out and exactly the right size are more efficient than any that can e cut out by hand alone and no other quality or thickness of ibber has been found which is more efficient than that pplied. It is not uncommon to see makeshifts employed, erhaps to the discredit of the device and for lack of renewal f stock. Further trials of a few varieties of plaster show aat none approaches in respect of efficiency the present ethod of utilising a solution of rubber in naphtha, indeed, o plaster yet tried has remained in place for more than six ours without becoming soaked through. When the rubber olution becomes too thick by evaporation the addition of a mall quantity of naphtha or benzine well stirred in it will mprove it.

It is common now to perform any washing out that may be ecessary by means of a catheter introduced either through he penis or through the top of the glass, the excess lotion eing allowed to flow off through the exit tube. Patients ake their bath after the rubber tube has been detached without having the rest of the dressing removed. It is also ound that continuous irrigation of the bladder is easy to rrange. There are, however, no results from this method of treatment to record at present, but *a priori* one would expect a good deal of benefit from it in certain cases, especially in those in which phosphates are deposited in the bladder. Increased experience shows that five days and not four is the average minimum period for the dressing to remain efficient without needing attention. At the end of this time it is good practice to omit it for 12 or 24 hours, so that the skin and the wound may be well cleaned up before the dressing is reapplied, but this is by no means essential. Phosphates may be removed from the glass at the same time by soaking it in dilute hydrochloric acid. No cases of ulceration of the skin have been reported so far and in the only two cases in which the dressing failed ulceration sufficient to prevent the efficient application of the rubber solution was already present. In these two cases the device was a complete failure.

It would perhaps be as well to mention here that the common causes of overflow through the hole in the top of the glass are (1) the exit tube being at some part of its course above the level of this hole; (2) the exit tube being too long and the distal end being in consequence coiled up in the receptacle beneath the bed; (3) the exit tube being interrupted by a joint (this is unnecessary); and (4) syphonage occurring through the wool or gauze which is used to cover the top of the dressing having sagged down into the glass. No harm results from omitting this covering entirely. The dressing, unless working efficiently, is a trouble rather than a benefit to the patient, because the uncertainty renders it necessary to examine him frequently to see if he is wet and to dress his wound in both ways at once to insure his being kept dry. This means double the work. Sometimes a patient picks off the rubber in his sleep, but this is not a common cause of leakage. To cause the dressing to work efficiently certainly does demand a small amount of attention. The cause of the inefficiency is not far to seek as a rule, and when found and removed efficiency is insured and the patient remains dry with much less inconvenience and without any harm resulting so far as can be seen. The longest time so far during which the patient has remained dry from a single application of the dressing is a fortnight. When one considers that during that period by the old method the patient would have needed dressing about 100 times with a change of the draw-sheet each time, and very often with a change of his shirt as well, the practical utility of the device as a mere labour-saving machine and quite apart from the patient's comfort is obvious. The saving in cost of dressings during the fortnight would be between £2 and £3 and the saving of time to the nurse about 24 hours. The numbers of the separate pieces composing the complete set of apparatus have been revised in accordance with the demand. The various items can also be obtained separately.

In conclusion, I wish to thank all those who have reported their cases to me or who have allowed me to watch the progress of them. Such a system lends itself admirably to improvement in surgical technique, but at present the failures recorded are all too few and probably several points still remain to be elucidated as they arise.

WESTMINSTER HOSPITAL.

A CASE OF PUERPERAL ECLAMPSIA IN WHICH THERE WAS CESSATION OF THE URÆMIC SYMPTOMS AFTER REMOVAL OF CEREBRO SPINAL FLUID.

(Under the care of Dr. RICHARD G. HEBB.)

FOR the notes of the case we are indebted to Mr. J. A. Braxton Hicks.

The patient, who was 29 years of age, was admitted on May 26th, 1906, to the Westminster Hospital. The history of the illness was to the effect that since May 16th she had been suffering from the following symptoms: œdema of the feet, legs and face; severe and persistent frontal headache; passage of scanty high coloured urine; drowsiness; and just previously to admission "fits." She further stated that she was six months pregnant and that she had had five previous pregnancies, the last ending in a miscarriage at the third month. All the labours had been instrumental but there had been no other untoward symptoms. The family history was good and there was no previous history of fits. When first seen by the house physician, Mr. J. G. Gibb at 4.45 P.M. her condition was as follows. She was very drowsy and complained of headache; there was moderate œdema of the face and legs; the temperature was 98·4° F.; the pulse was of high tension; the second cardiac sound was accentuated and the first sound was reduplicated, but no bruit or enlargement of the heart could be detected. On examination of the abdomen the fundus of the uterus was found to reach to the level of the umbilicus and the uterus contracted under the palpating hand. The uterine souffle and fœtal heart were both heard. Bimanually the cervix was found to be soft; the os admitted a finger and fœtal parts and movements were felt. The urine was high-coloured and became semi-solid on boiling. It contained much serum albumin, a little globulin, hyaline and granular casts, red corpuscles, leucocytes, epithelium, and pigment granules. At 6 P.M. she had an epileptiform convulsion, attended with much cyanosis and preceded by a cry. The right side of the body was most affected. Chloroform was administered. At 8.45 P.M. she had another convulsion. Chloroform was again given and three laminaria tents were inserted into the cervical canal. After this there was frequent vomiting and morphine was prescribed. Next day (the 27th) at 7 P.M. the patient aborted. The placenta and membranes were detached by the finger. There was very little uterine hæmorrhage after delivery. During the night the temperature rose to 99·2° but by the next morning it was 98·4° and afterwards remained normal. On the 28th she had three more convulsions, two of which were fairly severe. Dr. Hebb then decided to try lumbar puncture as had been recommended by some for uræmic convulsions. Lumbar puncture was accordingly performed and at first the cerebro spinal fluid flowed into the test tube in a continuous stream instead of drop by drop as is normally the case. The fluid withdrawn measured 38 cubic centimetres; it was found to contain no urea but it reduced Fehling's solution, giving also glucosazone crystals. From the time lumbar puncture was performed till the patient left the hospital her condition rapidly improved. The drowsiness soon disappeared and the pulse tension diminished but the first cardiac sound remained reduplicated and the second sound accentuated. By the 31st the headache had entirely disappeared. On June 1st the top of the uterus could not be felt through the abdominal wall. On this day also the breasts began to secrete; the secretion, however, was scanty and needed no treatment save an absorbent pad and bandage. The lochia were never at any time offensive or excessive and they ceased on June 8th, as did also the mammary secretions. The total amount of urine passed and the percentage of urea soon reached normal. Each day the amount of albumin grew smaller and the casts diminished in number, so that by the time the patient was discharged, on the 13th, there was only the faintest cloud on boiling and the centrifuged deposit showed only a few hyaline casts.

Remarks by Dr. HEBB.—The case, which was perforce admitted to a medical ward owing to the paucity of beds on the obstetrical side, was first seen by Dr. Bertram L. Abrahams on May 26th and after consultation with Dr. George D. Robinson it was determined to empty the uterus. Though this was successfully accomplished the uræmic symptoms persisted but soon subsided after the withdrawal of the cerebro-spinal fluid, a result in accordance with cases recorded by others. This is the first opportunity which I have had of testing the value of this procedure and judging from the result the treatment certainly deserves further trial. There is no need to descant on the theories of uræmia in connexion with this case but it seems to me that should the withdrawal of cerebro-spinal fluid be frequently found to be followed by cessation or amelioration of uræmic symptoms the chemical view which now holds the field will have to be modified. The cerebro-spinal fluid was tested for urea but none was detected; a rough estimate was also made of the globulin in the urine with the result that it was found to be minute as against the amount of serum albumin. As already noted, the cerebro-spinal fluid reduced Fehling's solution and formed glucosazone crystals when treated with phenylhydrazin and sodium acetate. It was quite pellucid when withdrawn and the centrifuged deposit showed only three or four lymphocytes to the field of a one-sixth inch objective. I am much indebted to Mr. Gibb for his skilful and successful management of the case.

ST. LEONARD'S HOSPITAL, SUDBURY, SUFFOLK.

A CASE OF "REST GROWTH" IN A FLOATING KIDNEY; NEPHRECTOMY; RECOVERY.

(Under the care of Dr. EDGAR HUNTLEY.)

ON March 16th, 1906, Dr. Huntley was sent for by a stranger to go to see his wife who, instead of passing urine, had passed blood. On his arrival he found the patient to be a stout, florid woman, 66 years of age, who had been constantly employed for the last 34 years at laundry work in all its branches. She gave the following history. Both parents lived until over 80 years of age; a brother and a sister died from pulmonary tuberculosis and one sister from "dropsy." She herself never remembered being ill enough to call in a medical man until 18 months after her marriage when she gave birth to a stillborn child of seven months. She had never been pregnant since. Her periods had been perfectly regular and never copious. The menopause took place about the age of 48 years. For the last 30 years she had had pains in her back, which were worse on stooping and were always relieved by the application of bran poultices. She never noticed any difficulty in passing urine nor had there been any marked increase in frequency of micturition nor to her knowledge had she ever before passed blood.

On examination nothing could be discovered amiss in the chest but in the abdomen there was a large moveable mass mainly lying to the right side of, and below, the umbilicus. The patient was quite unaware of its presence. There was no tenderness about it and it felt very like a hard fibroid of the uterus. Being a little uncertain as to where this blood came from the vagina was first examined but no sign of blood was there. A catheter was then passed and no sign of blood or of urine was found, the bladder being empty. Nothing unusual was found in the rectum. Considering the quantity of blood in the utensil and the presence of the above-mentioned mass Dr. Huntley advised the patient's removal to hospital with the view of watching her. She was admitted on March 19th and kept in bed. No blood had been passed from the day she was first seen up to March 24th, when more blood was passed and this time there was no doubt that it came per urethram. Up to this time albumin and casts were absent from the specimen of urine passed and the quantity of urine averaged between two and three pints per diem.

Operation.—The patient having been carefully prepared she was given A.C.E. mixture by Mr. B. N. Molineux. Before opening the abdomen the mass could be moved about in any direction and did not have any tendency to return to the spot which it originally occupied. There was no evidence of ascites. The abdomen being opened and the mass brought up to the surface a very dark blood-stained and bruised-looking mass was evident with coils of intestine adherent all over the front of it. After great difficulty, owing to adhesions, the mass was found to have a large, thick pedicle lying at its posterior aspect. At this stage it was a question whether in existing circumstances it was right to proceed further. However, as no glands could be felt and the liver being free from any deposits, the coils of intestine were gradually and carefully peeled off the mass and the vessels ligatured *en route*. This took a very long time. The pedicle was tied and the lump was removed. It was only then that it became certain that the tumour was a kidney with a very large growth springing from it. There being now very little hæmorrhage the abdomen was closed, all clots being sponged out, and the left kidney was noted in place and feeling normal in size and consistence.

The patient made a most uneventful recovery and left the hospital for a convalescent home on April 24th. On her return three weeks after she was extremely well and had put on nearly ten pounds in weight.

Remarks by Dr. HUNTLEY.—As we were quite uncertain as to the nature of the growth springing from the kidney, and as I personally had not seen anything like it before, it was decided to send the whole mass for examination to the Clinical Research Association. In due course the report received was to the effect that the mass was a true adrenal rest carcinoma. Being somewhat rare, and Guy's Hospital Museum only containing one or two such specimens, the mass was halved, one portion being placed there and the other being kept here. So far as I can ascertain there is no mention of a like growth occurring with a floating kidney, but the mobility was in some respects a help at the operation, in so far as making it easier for removal. Should the mass have been fixed in the ordinary position it would have been most difficult to remove through a lumbar incision owing to the large size and many adhesions and the tearing of important structures almost inevitable. As it was I had plenty of room.

My task was much facilitated by Mr. Molineux's help as anæsthetist and by that of the nursing staff who acted as my dressers.

Reviews and Notices of Books.

A Text-book of the Practice of Medicine. BY JAMES M. ANDERS, M.D., Ph.D., LL.D., Professor of Medicine and Clinical Medicine at the Medico-Chirurgical College; Physician to the Medico-Chirurgical Hospital, Philadelphia. Illustrated. Seventh edition, thoroughly revised. London and Philadelphia: W. B. Saunders Co. 1905. Pp. 1279.

THIS text-book is probably better known in the United States of America than in this country but the fact that a seventh edition has been called for is sufficient proof that the efforts of the author have met with well-merited success. The work is intended to introduce the student to the present state of knowledge of medicine in general; especial emphasis, however, is laid on points affecting diagnosis and treatment. The differential diagnosis in many instances has been tabulated. There are 56 such tables scattered through the work and they will be found useful for rapid reference. The majority of the tables are full and accurate but occasionally omissions occur. In considering the diagnosis of disseminated sclerosis, for instance, paralysis agitans, locomotor ataxia, and hereditary ataxia are tabulated as presenting certain similarities to disseminated sclerosis, and the differential points are carefully stated. Syphilis of the central nervous system is also mentioned as being liable to give rise to diagnostic errors. On the other hand, the condition most likely to be mistaken for disseminated sclerosis—namely, functional disorder of the central nervous system—is not mentioned, nor is general paralysis of the insane.

For this edition the whole work has been thoroughly revised so as to include the more recent advances that have been made in medical knowledge. Certain new subjects have been introduced, such as myasthenia gravis and Rocky Mountain spotted fever, a disease which has been known for many years in the valley of the Bitter Root River in Western Montana and which has also appeared in Rock Creek and Bonito and in the valleys of streams situated in the mountainous sections of North-Western Nevada, Southern and Western Idaho, and in Northern Wyoming. Paragraphs have also been added on pseudo-tuberculosis, benign cirrhosis of the stomach, intestinal calculi, and the Adams-Stokes syndrome. Important additions have been made to the account of diseases which prevail principally in tropical and sub-tropical regions.

The book is well printed and there is a full index. We have no doubt that the present edition will meet with the popularity which has attended its predecessors.

The Operating Room and the Patient. By RUSSELL S. FOWLER, M.D., Surgeon to the German Hospital, Brooklyn, New York. Fully illustrated. London and Philadelphia: W. B. Saunders Company. 1906. Pp. 172. Price 10*s.* net.

THE author describes the conditions and arrangement at the hospital with which he is connected, and he appears to think that any different arrangements must be faulty. To our mind a rather large number of assistants appear to be thought necessary for an operation. Thus there are four operating-room nurses, which in addition to the anæsthetist and the anæsthetist's special nurse and an operating-room orderly make up quite a crowd. The operating staff consists of the operator, his adjunct, the house surgeon, and the senior assistant. Thus there are apparently 11 persons required for an operation. The author seems to be very fond of having furniture and basins and tables wiped with a solution of perchloride of mercury. Has he any proof that this wiping with an antiseptic has any advantage over simple cleansing? For anything that can be boiled boiling is far preferable to all other means of sterilisation. The lists of instruments for various operations are likely to prove useful. We are told that anesthal is "a chemic combination of ether, chloroform, and ethyl chloride"; we should be glad to know the evidence that it is anything more than a mixture. It sounds rather curious to be told that the required amount of ethyl bromide should be "poured into a small graduate."

The Microscopy of Vegetable Foods, with Special Reference to the Detection of Adulteration and the Diagnosis of Mixtures. By ANDREW L. WINTON, Ph.D., with the collaboration of Dr. JOSEF MOELLER. With 589 illustrations. London: Chapman and Hall, Limited; New York: John Wiley and Sons. 1906. Pp. 701. Price 31*s.* 6*d.*

THE identification of food products of vegetable origin by the microscopic structure and micro-chemical reactions of their tissues and cell contents is a branch of analysis which is somewhat neglected in this country although the application of the microscope to the diagnosis of foods and drugs so often proves a valuable aid to the detection of adulteration. Readers of THE LANCET will recall the revealings of the microscope in regard to the adulteration of food by THE LANCET Sanitary Analytical Commission in 1850 instituted by the founder of this journal. At that time, indeed, the microscope did more to lay bare the extensive adulteration that was being practised than did the test-tube. For all that, the modern analytical curriculum does not appear to attach that importance to microscopical methods of differentiation which we should have thought their value demanded. There are signs, however, of an awakening in this direction and English scientific literature, formerly so short of practical works on the subject, is, we are glad to find, being enriched with works on vegetable histology both in its pure and applied aspects. To the works of Hassall and Greenish, amongst others on the subject, we must now add the book before us which we estimate at once as so far the best, as it is the most comprehensive, contribution in the English language to the literature of the histology of vegetable foods.

As is acknowledged in the preface, the work is closely affiliated with the second edition of Moeller's "Mikroskopie der Nahrungs- und Genussmittel," which was published about a year ago with the collaboration of Dr. Winton who is in charge of the analytical laboratory of the Connecticut Agricultural Experiment Station. Thus, the description of the individual leaves, flowers, barks, roots, and edible fungi, with few exceptions, are translations of Professor Moeller's text and no less than 350 illustrations are due to the same source. The work is divided into ten parts, the first dealing with reagents, apparatus, the preparation of materials for examination, the histological elements (tissue and cell-contents), and the morphology of organs. The real business of the book is commenced in the second part, entitled "Grain: its Products and Impurities." Then follow chapters on oil seeds and cakes, legumes, nuts, fruit and fruit products, vegetables, alkaloidal products and their substitutes, spices and condiments, and commercial starches. A very valuable feature of these chapters is the profuseness and excellence of the histological and morphological illustrations which will be of the greatest assistance in the quest for foreign additions or adulterants. Apart from the food analyst, the agricultural chemist, or the pharmacist, the medical man will appreciate those chapters which throw light upon the methods of identifying vegetable substances in, for example, the contents of the stomach or in the dejecta. Throughout the directions are thoroughly practical. We think we have indicated enough to justify our cordial commendation of this latest and valuable addition to analytical literature.

Secrets of Lawn Tennis. By F. W. PAYN. London: L. Upcott Gill. 1906. Pp. 176. Price 2*s.* 6*d.*

IN this little work on lawn tennis Mr. F. W. Payn, a well-known exponent of this popular pastime, descants at considerable length, and with much acrimony, on the subject of diet, and at less length and with less acrimony, but probably with more knowledge, on the manner in which the game of lawn tennis should be played. It is unlikely that many authorities will disagree with the advice which the author offers on such questions as "passing strokes," "the stop volley," "the shoulder stroke," and the "follow through," questions which constitute for the most part the secrets which are divulged by Mr. Payn, but, nevertheless, when he enters into scientific explanations even on these very matters, in which he doubtless has great practical experience, we at once find ourselves in very serious disagreement with him. For instance, when he speaks of the "shoulder stroke" he compares the movements of the arm and racquet to the action of a lever of the third class, in which the fulcrum is at the shoulder-joint, the weight at the point of impact with the ball, and the power at some point apparently on a line which is formed by producing the axis of the arm through the body towards the opposite shoulder. Mr. Payn should study the anatomy and mechanics of the shoulder girdle before he identifies himself with ridiculous statements of this kind. We find the same fault with those parts, and they form the major portion, of the book which refer to the subject of diet. The general views in their practical relationships are, in our opinion, quite sound, but the theoretical and the scientific parts are little less than twaddle. On the subject of fatigue and "fitness" Mr. Payn writes at considerable length, but he devotes himself too exclusively to the muscular side of the question; the nervous side is relegated to a very subordinate position. "Fitness" cannot be secured by feeding muscles even on an ideal dietary; there is a very decided limit as to what food can do. Provided that the other factors in the environment are of the best possible character, there can be no doubt that neuro-muscular efficiency can be raised to a very high standard of efficiency on a vast number of food combinations which may or may not coincide with the views of different food specialists or food faddists. But neuro-muscular efficiency is, and must be, impaired by every variety of intoxication, whether of endogenous or exogenous origin, and to this condition gross errors of diet, indigestion, and over-stimulation of all kinds must clearly contribute; but to imagine that fitness can be secured and fatigue prevented by adhering to any one particular line of dietary is manifestly absurd.

Mr. Payn is very hard on some of the best known writers, on dietetics who disagree with him on the question of proteid metabolism. He appears to think that if man cannot live without meat at least he is all the better for a very restricted proteid intake; indeed, he even goes so far as to quote authorities in support of the statement that oleaginous principles of food can be built up in the animal economy and gradually converted into nitrogenised principles by combining with atmospheric nitrogen, and he thinks that this sort of process has taken place in his own body after a hard game of lawn tennis when six or seven pounds loss in weight has been made good by a nitrogen-free diet such as he enjoins. It does not appear to occur to this authority on dietetics that a large part of the loss in weight may have been due to a loss in water and of reserve stores of fat and glycogen and that the dissipation of fatigue, from which he so rapidly recovers under this *régime*, may be due to the physiological influence of rest.

Although, perhaps, we have been almost as severe in our criticism of the author as the author has himself been on several eminent medical authorities, nevertheless we must admit that the "Secrets of Lawn Tennis" is a very readable little book and that the practical hints on play will probably be most useful to those concerned.

LIBRARY TABLE.

Course of Instruction in Operative Surgery in the University of Manchester. By WILLIAM THORBURN, B.S. Lond., F.R.C.S. Eng., Lecturer in Operative Surgery. Manchester: At the University Press. 1906. Pp. 75. Price 2*s.* 6*d.* net.—This is a volume of the medical series of the publications of the University of Manchester and as it gives the regulations in use in the operative surgery class there it is obvious that it is primarily intended for local use, but it can be used with any operative surgery class. The book is based on notes which the author has been in the habit of providing for his class for each day's work. They tend, he finds, to the smooth and rapid working of the class and therefore he has published them. He tells us that these notes are only intended to draw the students' attention to the main points of the operation to be performed and are not intended to replace any of the ordinary text-books on operative surgery. This explanation by the author disarms criticism and for the purpose intended the book should prove useful. Space is provided for notes by the student but we doubt very much if the average student will use these blank sheets.

Portfolio of Dermochromes. By Professor JACOBI of Freiburg in Breisgau. English adaptation of text by J. J. PRINGLE, M.B. Edin., F.R.C.P. Lond., Physician to the Department for Diseases of the Skin at the Middlesex Hospital, London. Supplement containing 76 additional coloured illustrations. London: Rebman, Limited; New York: Rebman Company. 1906. Forty plates; pp. 72. Price, loose plates, 25*s.* net; half roan binding, £1 8*s.* 6*d.* net; full roan binding, £1 11*s.* 6*d.*—The previous volumes of this work were excellent examples of colour printing and this supplement is no whit behind them in quality of production. The plates are taken from wax models and they represent very accurately the morbid conditions. The four-colour process employed is a very definite advance on most three-colour methods and it is difficult to see how the results can be surpassed. The English adaptation of the text by Dr. Pringle is admirably done.

National Conference on Infantile Mortality. Report of the Proceedings of the National Conference on Infantile Mortality, held in the Caxton Hall, Westminster, on June 13th and 14th, 1906. Westminster: P. S. King and Son. 1906. Pp. 314. Price 1*s.* 6*d.* net.—The report of this national conference, over which the Right Hon. John Burns presided and of which Mr. Evan Spicer, the chairman of the London County Council, was the chairman, contains much of real interest to the community. The idea of the conference originated among the British delegates to Paris in October, 1905, who attended the International Congress on the Functions of Infants' Milk Depôts. So deeply impressed were the British visitors with the vigour with which France is attacking the question of infantile mortality and so great seemed to them the contrast which this presented with the apathy towards the question existing in this country that a requisition was prepared and addressed to the representatives of certain corporations suggesting that they should take steps to convene a national conference on the subject. The conference of which this volume is a record is the outcome of that requisition. A public recognition of the excessive infantile mortality has now been obtained and of the fact that although some of its causes need little more than recognition in order to be removed, in essence it arises from causes which lie deep in the social and economic conditions of the people. The book contains a list of the office-bearers and members, the President's inaugural address, and the following papers: 1. The Teaching in Schools of Elementary Hygiene in Reference to the Rearing of Infants, by Dr. James Niven. 2. The Appointment of Qualified Women, with Special Reference to the Hygiene and Feeding of Infants, by Dr. J. Spottiswoode Cameron. 3. The Public Supply of Pure or Specially Prepared Milk for the Feeding of Infants, by Dr. G. F. McCleary. 4. Premature Birth in Relation to Infantile Mortality, by Dr. J. R. Kaye. 5. Alcoholism in Relation to Infantile Mortality, by Professor G. Sims Woodhead. 6. Ante-natal Causes of Infantile Mortality, including Parental Alcoholism, by Dr. J. W. Ballantyne. 7. The Teaching of the Hygiene of the Expectant and Suckling Mother, by Dr. John F. J. Sykes. 8. Earlier Notification or Registration of Births, by Alderman B. Broadbent, Mayor of Huddersfield. 9. Memorandum on the Earlier Registration or Notification of Births, by Dr. E. W. Hope. 10. Infant Life Insurance, by Councillor W. F. Anderson. 11. Infantile Mortality and Life Insurance, by Mr. F. Schooling. 12. Infant Mortality and the Employment of Married Women in Factory Labour Before and After Confinement, by Dr. G. Reid. 13. The Regulation of the Placing of Infants out to Nurse, by Dr. S. G. H. Moore. 14. The Amendment of the Infant Life Protection Act, by Dr. A. Greenwood. 15. The Chemistry of Infant

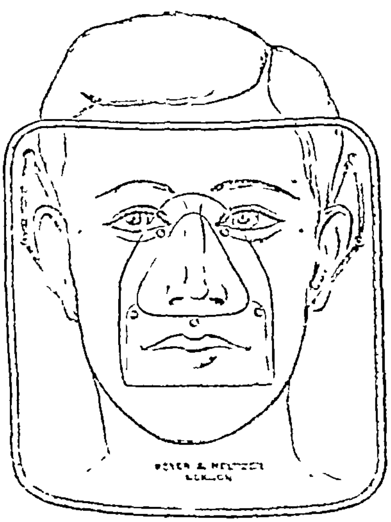
Foods, by Mr. J. Knight, D.Sc. 16. Increase of the Powers of Local Authorities with Regard to Milk-supply, by Dr. A. K. Chalmers. 17. The Operation of the Midwives Act in England, with a view to its Extension to Scotland and Ireland, in Relation to Infantile Mortality, by Dr. Margaret M. Smith. The papers were followed in turn by a series of resolutions.

Questions and Answers on Nursing for the St. John Ambulance Associations, and Others. By JOHN W. MARTIN, M.D. R.U.I. Fifth edition. London: Baillière, Tindall, and Cox. 1906. Pp. 138 Price 1*s.* 6*d.* net.—In this, the fifth, edition of this little book a change has been made in the type in which the questions and answers have been printed; by the change the author hopes the reader will be helped in fixing both more easily in his memory. The book has been revised and some additions have been made. The author has adhered closely to what is required by the St. John Ambulance Association in the examinations conducted under its auspices. Many of those who are studying nursing will find the book helpful in fixing points of importance and interest upon their memories. It is a useful work. On p. 78, in the answer to the third question, we suppose the word "teacup" is wrongly printed for "teapot."

New Inventions.

FACIAL PROTECTIVE MASK.

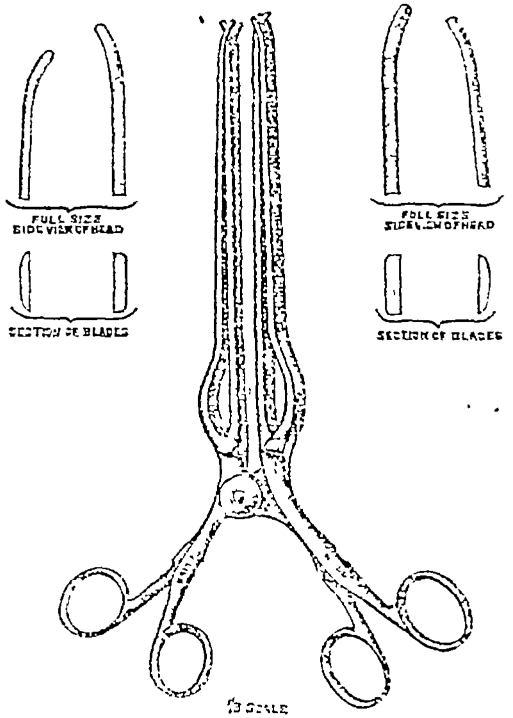
THE frequent liability which those engaged in throat work incur of having the face spat upon and bespattered with visible and invisible expectoration and the toleration with which this has been endured by the faculty would almost persuade one that such can always occur with impunity. It is obvious, however, that the risks of contracting the foulest disorders while examining and treating many pharyngeal and laryngeal affections are great and many. The apparatus that have from time to time been invented to minimise these dangers have never been universally adopted because of their expensiveness, clumsiness, and awkwardness for ready, quick adjustment. I have found this facial protective mask efficient, and so easy of application that it accomplishes the objects desired. Being composed of mica it is sufficiently light and transparent and can be washed and sterilised by boiling. It is very easy of adjustment, since it is simply looped over the ears by means of two elastic bands. The mask has the additional merits of durability and cheapness. Messrs. Mayer and Meltzer, 71, Great Portland-street, are the makers.



W. STUART-LOW, F.R.C.S. Eng.

NEW GASTRO-ENTEROSTOMY CLAMP.

THE accompanying illustrations show a new pattern gastro-enterostomy clamp which Messrs. Weiss and Son, Limited, of 287, Oxford-street, London, W., have made from my drawings. The clamp is a twin clamp and consists of two forceps; each forcep consists of a male and female blade. The male blade is straight and fits by an easy mechanical contrivance into the female. Both blades are grooved longitudinally, so that when they are closed they take a firm grip of the mass of tissue between them and do not in any way injure it—in fact, they do not even mark the tissues. The female blade has a double curve, a long one reaching from the tip to the beginning of a short, sharp curve. The length of this long curve is five inches and its outer surface is marked off in a quarter-inch scale, by means of which the length of the incision in the stomach and bowel can be exactly measured, a point of the greatest importance as regards the neatness of the operation. The length of the clamp is about 11 inches. When the blades are closed on the mass of stomach or bowel the female blade presses the tissue against the male blade (there is no compression); it perfectly steadies the tissues and acts also as a hæmostatic forceps. When the forceps are opened for removal there is no tension on the three lines of suture already introduced, and the obtuse angle which the handles make with the blades gives room for both sides of the anastomosis to be examined with the forceps in position, which cannot be done with the twin forceps in which the blades are straight. I claim the following advantages for this clamp over those at present in use. These various points are well shown in the illustrations. (1) It is lighter and can be used without rubber coverings; (2) it acts as a hæmostatic forceps; (3) the inch scale enables the incisions to be measured accurately; (4) the bent position of the handles allows all parts of the anastomosis to be examined while the clamp is in position; (5) opening each blade of the forceps does not put the sutures on the stretch as some of the present modes do; and (6) it can be used for any sort of entero-anastomosis as well as gastro-enterostomy. I have to thank Messrs. Weiss and Son for the very careful way in which they have carried out my designs and suggestions.



T. GELSTON ATKINS, M.D., M.Ch. R.U.I.,
Surgeon, Cork South Infirmary.

THE BRITISH MEDICAL ASSOCIATION.

MEETING AT TORONTO.

(From our Special Correspondents.)

THE SECTIONS.

ANATOMY.

Tuesday, August 21st.

The President of this Section was Professor **Arthur Robinson** (Birmingham) who delivered an address on

The Study and Teaching of Anatomy.

He said that there were systems of teaching anatomy which tended to obscure the wide scientific interest of the subject and to reduce it to a merely technical standard. This technical aspect was tending to become even more prominent owing to the increased demands which were made upon the student's time. Fortunately, there had always been in the medical profession many broad-minded men who had recognised that the man who had a wide knowledge of general principles was better adapted to meet unexpected circumstances than one who was merely provided with the memory of a certain number of observed facts, and fortunately the opinions of their broader-minded colleagues had hitherto prevailed. The result had been that in a large number of well-equipped medical schools and medical departments of universities the teaching of anatomy had passed into the hands of specialists —that is, into the hands of men who had spent the greater part of their lives in the study of the subject, and who were enthusiasts in its teaching, looking upon man as the highest outcome of nature and considering him and his relations as worthy of the most careful study. Still, though this was a movement in the right direction it must be borne in mind that there was a danger that specialists sometimes might lose sight of the practical applications of their subject and work at, and teach only, its more scientifically accurate features. The danger would be avoided if the electing bodies of teaching institutions would elect only those men who had been through the medical curriculum and who understood the needs of the profession and of the students, and if the men thus appointed would keep in touch with their colleagues who were practising the art of medicine and surgery. The object of a medical curriculum should be to give the men passing through it a wide knowledge of the principles on which they must rely in the practice of their profession, a sufficient knowledge of the details, and finally an understanding of man's place in nature and his relationship to nature's general laws. It should therefore be the object of anatomists to avoid entangling medical students with a superfluity of detail. They should insist upon a sound knowledge of the general relations and arrangements of the more important organs and parts of the body and a good knowledge of the general principles which underlie these relationships. They should endeavour to make their students acquainted with the general laws of growth and development, and carrying on the work done in the biological department, they should draw attention to man's relations to other animals in all cases where such relations were evident and were instructive of the methods by which man had been evolved. In conclusion Professor Robinson remarked: "I would strongly urge that if we wish to do well for our medical students and the medical profession as a whole we should deal more with general principles and less with detail than has generally been the case in the past."

Professor **J. Playfair McMurrich** read a paper entitled

A Preliminary Note on the Valves of the Iliac Veins.

He said that he had found that in a certain percentage of 30 cases examined valves were present in the external iliac veins. The valves varied both in number and completeness. In the common iliac vein, near its termination, there was a tendency to fusion of its anterior and posterior walls, and in one case along this line of fusion perforation of the adherent walls had occurred so that the vessel was divided into two parts for a short distance. It was suggested that both the valves in the external iliac vein and the fusion of the walls in the common iliac vein might have some influence in causing thrombosis.

The **President** remarked that possibly the high percentage which Professor McMurrich had found would have to be modified later, for in six cases which he had specially examined no valves were present.

Professor **G. Carl Huber** (Michigan) demonstrated with lantern slides

The Origin of the Arteriæ Rectæ of the Mammalian Kidney.

He showed that all the arteriæ rectæ were efferent branches of glomeruli. This was important in that they now knew that all the blood passing to the different parts of the uriniferous tubules was blood that had first passed through the glomeruli, therefore altered blood, a point which physiologists must take into consideration in discussing the secretory activity of the kidney tubules.

Professor **Huber** then exhibited a second series of slides showing

The Form of the Uriniferous Tubules of Certain of the Lower Vertebrates.

The character of the duct system and the form of the uriniferous tubules of different forms of reptiles (turtle, snake, lizard, and alligator) were discussed. As there was no pelvis in the reptilian kidney the ducts were easily worked out by injection. The form of the tubule was ascertained by the wax-plate reconstruction method. The tubule in all the forms studied consisted of a small Malpighian corpuscle, a short neck, a simple proximal convoluted portion, a short narrow segment with low epithelium, and a portion which might be known as a distal convoluted portion —facts similar to those found in the mammalian tubule, although there was no loop of Henle.

Professor **McMurrich** suggested that the corrosion method employed by Professor Huber might with advantage be applied to work on other organs.

Professor **H. H. Donaldson** (Chicago) then read a paper on behalf of Dr. **S. Walter Ranson.**

On the Architecture of the Spinal Ganglion.

He described how on the section of the dorsal ramus of the second cervical nerve of the white rat—which contained about 87 per cent. of all the afferent fibres belonging to this spinal nerve—it was found that the subsequent chromatolysis affected more than 80 per cent. of the 8000 cells in the associated ganglion. Two months after the operation it was found that some 4200, or 52 per cent., of the cells had degenerated and disappeared. The disappearing cells were for the most part those of small diameter. This loss of cells followed a section of from 1500 to 2200 medullated fibres and hence the fact that from two to three cells disappeared as the result of cutting each medullated fibre called for explanation. The most plausible hypothesis was that these degenerating cells were represented in the nerve by unmedullated fibres and degenerated as the result of the section of these fibres. The search for these hypothetical fibres was in progress. Under the title "Retrograde Degeneration in the Spinal Nerves," the principal data had been published in the *Journal of Comparative Neurology and Psychology*, vol. XVI., No. 4, 1906.

Professor **Huber** and other members joined in the discussion.

Dr. **R. R. Bensley** then gave the results of his work on three subjects, the first of which was

The Structure of the Cardiac Glands of Mammals and their Phylogenetic Significance.

From the study of the so-called cardiac glands in various mammals Dr. Bensley had come to the conclusion in 1903: 1. That the cardiac glands are mucous glands. 2. That the cells of the cardiac glands are fundamentally different from the chief cells of the body of the fundus gland, inasmuch as the latter contain two characteristic substances recognisable by staining and micro-chemical reactions, which are the chemical antecedents of their secretion—namely, the zymogen granules and the prozymogenic basal filaments. Both of these substances are absent from the cells of the cardiac glands. 3. That the cardiac gland cells are closely related to the mucous chief cell of the neck of the fundus gland and to the pyloric gland cell. 4. That the cardiac glands are decadent or retrogressive structures derived from fundus glands by the progressive disappearance of their most highly differentiated elements, the chief cells of the body of the gland and the parietal cells. In two recent articles Haane had arrived at conclusions which were the exact opposite of Dr. Bensley's—namely, that the cardiac glands were non-muciparous structures which differed from the fundus glands and from the pyloric glands and which were physiologically important, inasmuch as they secreted an amolytic ferment. The work on which this paper was based had been undertaken with the object of determining which of these conflicting views was correct and had, Dr. Bensley considered, fully confirmed the conclusions at which he had previously arrived. That the cardiac glands were mucous glands was evidenced by the fact that in every case examined the secretory contents of the cells of these glands was stainable with muchæmatein and with mucicarmine, and, further, the gradual transition in the type of cells between the foveolæ and the bottom of the gland indicated a close relation between the cells of the surface epithelium and those of the gland which would lead one to suspect their mucous properties even if the confirmatory stains could not be obtained. That Haane was unable to stain the cells of the cardiac glands of the pig with muchæmatein and mucicarmine was, Dr. Bensley believed, probably due to difference in technique, as he himself was always able to get positive results. In discussing the results obtained by Haane in the cardiac glands of the ox, sheep, and goat respectively, the fundamental question to be answered was that dealing with the homogeny of these structures. For if the glands occupying the area between the psalterium and glandular portion of the stomach had been derived from the same antecedent structures by the operation of the same factors, then the differences which might be observed between them were not fundamental in nature.

The second subject considered by Dr. BENSLEY was

The Cytological Characters of the Cellular Components of the Islands of Langerhans.

Dr. Bensley and Mr. Lane were of the opinion that the cells composing the islands of Langerhans were definite and quite distinct from the alveolar cells. In the pancreas of the guinea-pig chromophile cells were present which stained with neutral gentian. These cells were large and somewhat branched; the nucleus contained nucleoli which were oxyphile. The ordinary cells of the islets were clear. In rodents and ungulates these cells were fairly abundant and could easily be distinguished by their type of nucleus from the centro-acinar cells.

Professor HUBER remarked that it was possible to distinguish the alveolar cells by ligaturing the pancreatic duct and thus producing changes in these cells.

The third subject discussed by Dr. BENSLEY was

The Structure of the Lacrymal and Harderian Glands of Mammals.

He described the character of the cells in different parts of the gland tubules of the ox and sheep. By employing different methods of staining several types of cell could be distinguished. Near the duct the cells were small and granular, at a point nearer the fundus of the gland the cells were larger and more complex, while the cells at the bottom of the alveolus were still more complex, notwithstanding the fact that the lacrymal secretion was chemically a very simple fluid. The specimens were stained with "neutral gentian" and other reagents.

Professor DONALDSON drew attention to the cells of the ependyma in the cerebral ventricles which also secreted a simple fluid and were very similar in structure. He remarked also that the nucleus in these cells shifted its position after birth.

WEDNESDAY, AUGUST 22ND.

The proceedings were opened by a paper read by Professor A. MELVILLE PATERSON (Liverpool) on

The Ligamentous Supports of the Pelvic Viscera.

He remarked that from observations on the human subject, living and dead, and by dissections of various mammals, it was apparent that the accepted description of the pelvic fascia and of its relations to the pelvic viscera was altogether erroneous. Both in the male and the female the rectum was wholly unconnected with the pelvic fascia down to the anal canal. It occupied a rectal channel and was enveloped by a dense layer of extra-peritoneal tissue devoid of fat. The rectum was thus able to distend and to collapse without being affected by the conditions of the genito-urinary organs. The genito-urinary organs (prostate in the male, urethra and vagina in the female) were fixed and suspended by a bilateral suspensory ligament which swept forward from the ischial spine and split to inclose the organs. On each side these organs lay in contact with the levator ani and the fascia covering its pelvic surface. The bladder in both sexes and the uterus in the female were intra-pelvic organs. This suspensory ligament was highly vascular. On each side it was provided with a channel for the vesical vein; anteriorly the fascia was split into several layers by the prostatic plexus and the free crescentic fold of the fascia was particularly vascular on account of the accumulation of veins passing to join the internal iliac veins. The vessels were contained in sheaths among the layers of the fascia, and not between the fascial sheath and the prostatic capsule. The layers of the suspensory ligament were upper and posterior. The upper layer was traceable in continuity with the lateral and anterior true ligaments of the bladder. The posterior layer passed between prostate (or vagina) and rectum and was attached to the perineal body at the base of the triangular ligaments.

Professor W. S. MILLER read a paper on the Distribution of Lymphoid Tissue in the Lungs.

Dr. DAVID WATERSTON (Edinburgh) read a paper entitled

A Preliminary Note on the Brain and Skull in Mongolism.

He briefly pointed out the principal features, clinical and anatomical, which were distinctive of the condition of congenital imbecility known as mongolism. The examination of a series of brains and of an entire skull showed certain distinct and characteristic changes. The cerebral hemispheres were, in all, large and well convoluted. The orbital surface of the frontal lobe remained very oblique, however, instead of becoming nearly horizontal in position, the insula was not completely covered over by the opercula, and the first temporal convolutions remained small and failed to share the general cerebral development. The cerebellum, medulla, and pons Varolii were usually small in proportion to the cerebrum. The changes in the skull were described and analysed.

Professor DONALDSON called attention to the fact that during the later months of intra-uterine life the relative weight value of the cerebellum and brain stem increased and that the percentage value of these portions might indicate the age at which the normal growth processes had been first disturbed.

Professor C. R. BARDEEN gave a lantern demonstration illustrating

The Development of the Ova of the Toad, Fertilised by Spermatozoa which have been exposed to Roentgen Rays.

He said that ova which were fertilised by spermatozoa which had been exposed to the x rays, apparently developed in the early stages normally, no alteration being observable in the method of segmentation. At the time when the embryo was beginning to take form, marked differences were to be noted in the development of the central nervous system, the sense organs, and in the vascular system, and not infrequently monsters were developed. The results of the experiments showed that the spermatozoa might be affected by external conditions. If spermatozoa were removed from the body they usually lost their power of fertilisation within a few hours. If exposed to x rays this power was lost earlier. Speaking generally, the effects were observable chiefly in those organs in which the cells underwent the highest differentiation.

Dr. BENSLEY, Professor PRIMROSE, and Professor DONALDSON joined in the discussion.

Dr. G. L. STREETER (Baltimore) gave a brief report on

Some Experiments on the Developing Ear Vesicle of the Tadpole.

He described the development and behaviour of tadpoles following unilateral and bilateral removal of the ear vesicle and acoustic ganglion. At the time of operation the larvæ were three millimetres long; they were then followed in their growth up through the metamorphosis. The results of these experiments demonstrated that in tadpoles the ear vesicles were the essential factor in equilibration and secondly one ear vesicle was capable of performing the work of both, but when both were removed no other organ was able to compensate for their loss. The ear vesicle when transplanted to some other part of the body continued in its histological development but gave no evidence of establishing functional relations with the brain.

Dr. GEORGE J. JENKINS (London) read a paper on

The Morphology of the Hip-joint.

He stated that in the human embryo up to 2·7 centimetres in length there was a primitive acetabulum formed of ilium and ischium, the os pubis being kept out of the fossa by a mass of prechondral mesoblast. Eventually the os pubis formed part of the acetabular cavity as in the adult. There were three membranous defects in the margin of the cartilaginous acetabulum. The ischio pubic defect was partially obliterated by the growth of ischium forming the floor of the cotyloid fossa. The ilio-pubic and ilio-ischial notches were almost entirely obliterated by growth of the iliac cartilage. The growing margins of the cartilages were indicated in a reconstruction model of the joint in a 3·2 centimetre embryo by ridges. In the 1 8 centimetre embryo the head was represented by a prechondral cap on the upper end of the chondrified shaft. There was a relatively large flattened area on the head which was in the morphological position of the impression for the ligamentum teres of the adult. The capsule of the joint in the adult consisted of true and false capsules. The latter was derived from extra capsular structures. The true capsule of perichondral origin consisted of two parts, a primary part which was attached about the margin of the primitive acetabulum and a secondary part which was formed when the os pubis had advanced into the joint. The ligamentum teres was a part of the primary capsule and contained only a small amount of extra-articular tissue. The retenacular bands were formed in association with three groups of nutrient vessels passing to the head of the femur. The antero-inferior and postero-inferior bands had an origin in the mass of loose tissue found on the inferior aspect of the neck in young embryoes. The cells of the synovial membrane were derived from extra-articular mesoblast and invaded the skeletogenous mesoblast in a layer several cells thick. Up to the time of the invasion the anlage of the innominate bone was continuous with that of the femur and this invasion of external mesoblast might be regarded as the means of separating the innominate bone from the femur.

Dr. R J. GLADSTONE (London) gave a description of

A Symmelian Monster (Sympus Dipus).

He said that the two lower limbs were fused so as to form a single median lower limb. Each lower limb was rotated outward so that the patella was behind and the heel directed forward. The peroneal borders of the two lower limbs were fused along the middle line of the composite limb. There was an imperforate penis but no anus. The colon ended in the urinary bladder; there was thus a persistence of the cloacal stage of development. The kidneys and ureters were absent but the suprarenal bodies were present and had the normal histological structure. The main artery of the abdomen divided into a large artery which passed into the umbilical cord and a vessel which ran down the front of the vertebral column and divided into external iliac arteries. The renal arteries were absent. The innominate bones were dislocated from the sacrum and bent forward. They were united together by their posterior borders. The tuberosities of the ischia and the ischial and pubic rami were also fused, so that there was no perineal region and consequently no anus or urethra. Dr. Gladstone believed the condition to be due to a fusion of the post-axial borders of the limb buds over the cloacal area.

Professor O. J. PATTEN (Sheffield) gave a lantern demonstration on

A Series of Gorilla and Chimpanzee Skulls.

He demonstrated variations in the contour of the face and cranium in the chimpanzee and gorilla at different ages. In the chimpanzee the face might be narrow or broad. The males on an average were broader in the face than the females, but this was by no means a safe guide in distinguishing the sex. In broad-faced forms of this ape the lateral horizontal diameter of the orbit often exceeded the vertical, and the supraciliary ridges were on the whole more strongly developed. In the gorilla, most of the skulls, with the exception of adult males, had a vertical diameter of the orbital rim slightly exceeding that of the lateral horizontal diameter. In the skulls of young gorillas there were several distinctive characters by which they differed from adult skulls, notably in the breadth between the parietal eminences and in the length between the external angular process and the external occipital protuberance.

Dr. ROSS E. HARRISON read a paper on

The Development of the Nerve Elements in Vertebrates

Two main questions had to be solved: (1) Is the constitution of a nerve unicellular or multicellular? and (2) If unicellular, whence is the nerve fibre derived? Dr. Harrison first drew attention to the futility of attempting to solve these questions entirely by embryological methods, and to the necessity of experiment. Any part of a nerve might be removed or transplanted, and thus the environment of a nerve might be altered. From experiments, such as removal of the neural crest on one side in an early stage of the development of the central nervous system, Dr. Harrison concluded that the nerve was an outgrowth of the ganglion cell and that the sheath cells took no part in its development. If a portion of the spinal cord was transplanted nerves would grow out from it into mesenchymatous tissue. A limb bud might be transplanted from the body of one embryo to that of another; it would then acquire a system of nerves which was similar in its distribution to that of the normal limb. The nerves which connected the transplanted limb bud with the central nervous system were very small. It was found possible to examine under an immersion lens the cut ends of a nerve which had been divided. The ends were seen to come together and unite in about 24 hours; degenerative changes took place in the peripheral nerves but if a connexion was established between the cut ends within 72 hours the degenerative changes were arrested.

The PRESIDENT, Professor MCMURRICH, Professor DONALDSON, and Professor BARDEEN joined in the discussion which followed.

Professor THOMAS G. LEE (Minnesota) read a paper on

The Early Development of Geomys Bursarius.

He said that geomys was a genus of small rodents belonging to the family geomyidæ, all members of which family were peculiar to North America. Geomys bursarius, or the "pocket gopher" as it was commonly called, was found in the Mississippi valley, lived under ground, was strongly photophobic, rarely came to the surface, and was characterised by large cheek pouches which opened externally. Professor Lee, after several years of collecting, had succeeded in obtaining an unbroken series of pregnant uteri in all stages of development. Many of the following points were peculiar to geomys and differed from corresponding stages so far described for any other mammal, while in other features geomys showed many resemblances to several of the other rodents. 1. Geomys developed entirely outside the uterine cavity in a decidual cavity formed in the ventral portion of the uterine mucosa. In this it resembled the guinea-pig among rodents and also resembled the human development. 2. The blastocyst at the time of the perforation of the uterine epithelium was rather large. It was didermic, consisting of the trophoblast, which was continuous with the margins of the germinal area, and of an entodermal vesicle which nearly filled the blastocyst. Rauber's layer would seem to be lost at the time of, or shortly after, perforation. 3. The decidual cavity was formed by contact of the trophoblast with the ventral portion of the uterine mucosa, this bringing about a softening and destruction of the connective tissue. In the outer walls of this cavity there was developed a very large number of capillary blood-vessels which later became intimately associated with the yolk sac placenta. 4. At the point of rupture the epithelium bordering the opening became slightly everted and this opening did not close up as in the guinea pig nor did it become filled with a fibrin clot as in man, but it remained open and the epithelium cells were practically unchanged until later in the development when they became destroyed by the trophoblastic tissue of the fœtal placenta. 5 The trophoblast became adherent to the everted epithelial margin of opening in a zone somewhat external to the germinal area. This occurred at the time of the escape of the blastocyst from the uterine lumen. 6 There was the so-called inversion of layers. The germinal area sank into, and invaginated, the entodermal vesicle or yolk-sac, this cup-like structure being suspended by the adhering trophoblastic zone noted above. The cavity of the uterus was for the time being continuous with the inner portion of this cup. 7. The amnion was formed by a folding over of the outer margin of the germinal ectoderm, the adjacent trophoblast forming the serosa or false amnion which now separated the uterine cavity from the extra embryonic body cavity. 8 The trophoblastic layer constituting the false amnion now underwent a folding over similar to the formation of the true amnion. The edges of the folds united to form a two-layered rather rounded plate of trophoblast which now constituted the fœtal placenta. 9. This placental plate where it came in contact with the uterine

urea, he said, might appear low by iodide of potassium excretion as calculated by colorimetric tests. In the future the administration of the drug might prove of value as a guide of the renal competency.

Professor F. B. TURCK (Chicago) described with diagrams his experiments on

The Pathogenesis and Pathology of Ulcers of the Stomach.

Duodenal and gastric ulcer could be produced by feeding dogs with the bacillus coli communis for variable periods. This observation for the first time afforded a basis for the real etiology of peptic ulcer. Agglutination could be obtained in the blood to bacillus coli communis of the dogs which had thus been fed.

The Forms of Arterio-sclerosis.

A joint meeting with the Section of Medicine was then held, at which a discussion on this subject was opened by Professor W. H. WELCH (Johns Hopkins University). The various types of the disease were fully described as met with in Professor Welch's experience and the address was received with applause.

Dr. KLOTZ (McGill University, Montreal) described his experimental work with adrenalin in conjunction with vasodilator drugs on the arteries. The experimental arterial lesions produced in animals were of two kinds, either a degenerative one, affecting mainly the media, or a regenerative one, in which the intima proliferated, while little or no degenerative change was seen. It was found, too, that the substances which were used to produce the former belonged to the class of high-pressure drugs, but at the same time it was likely that the high pressure did not itself lead to the medial lesions noted; there was a distinct degenerative action of the drug on the muscle fibres of the media. Elastic fibres became affected later. The latter once giving way led to aneurysmal dilatation. The degeneration was of a fatty nature. The intimal regeneration was consequent to bacterial toxins, the proliferation being confined to the endothelial and subendothelial cells. When only intimal lesions were present aneurysms were not formed. In man lesions of a degenerative nature were met with in the Moenckeberg type of peripheral arterio-sclerosis and with the form of this disease as it was found in the aorta, both of which processes were confined to the media. The experimental bacterial lesions of vessels simulated the endarteritis chronica deformans which developed pearly intimal plaques. Adrenalin was a selective drug on the muscle of the circular coat and produced calcification and aneurysms in from two to three weeks. In the bacterial lesions cultures of a low virulence were used.

The PRESIDENT showed most interesting lantern slides illustrating his work on arterial lesions. One section showed distinctly *bone* metaplasia in an artery in which marrow cells were present. He considered that the degree of damage to the media determined the degree of reaction in the intima, repeating Sunikaya's experiments on the aorta. If the damage was too severe there was no reaction. Damage to elastic lamina followed severe damage of muscle fibres and necrosis.

Professor L. ASCHOFF (Marburg), who spoke in German, was warmly greeted. He gave his findings as to the distinctions of arteries according to their functions, whether peripheral or central.

Dr. PEARCE (Albany) continued the discussion. He said that experimental lesions were of great value in explaining degenerative and regenerative changes in vessels. The physiological study of the action of adrenalin was of great value in explaining the problem of cardio-vascular pathology. He believed that a temporary ischæmia in capillary areas produced lesions in the heart and blood-vessels.

Professor T. CLIFFORD ALLBUTT (Cambridge) said that he came to the discussion as a learner and spoke only from the clinical aspect. Arterio-sclerosis was a purely pathological term and Professor Welch in opening the discussion had shown how this term should be used. Adaptation of arteries might be regarded as the yield of the normal resources of the body to mechanical causes, such as pressure. Four or five years were taken for the cardio-vascular system to take on adaptation. Compensation was left behind.

Professor ADAMI regarded arterio-sclerosis as a reaction on the part of the vessel. The types of arterio-sclerosis were grades of this disease.

Professor WELCH, in reply, said that he was much interested to hear Professor Aschoff's views as to the distinctions of arteries according to their function, which agreed with his own observations. As to the propriety of the use of the word "adaptation," he agreed with Professor Clifford Allbutt.

Dr. ARMAND RUFFER (Cairo) contributed a valuable paper on

The Diagnosis of Cholera Asiatica.

His experiences in Egypt in connexion with the quarantine of pilgrims in that country was that cholera vibrios in the dejecta were not a danger, though bacteriologically they were cholera. The clinical side in diagnosis was of high importance.

Miss AMOS SHELDON (Alexandria) and Professor FLEXNER (New York) also spoke.

FRIDAY, AUGUST 24TH.

The meeting commenced by a demonstration by Professor F. G. NOVY and Professor R. E. KNAPP (Ann Arbor) of beautiful lantern slides illustrating

The Nature of Spirochætæ.

The organism was obtained from a case of relapsing fever which occurred in New York in 1905 and was described by Dr. Carlisle. It differed from that of the Bombay spirillum in being apposed end to end with a single terminal flagellum, whereas the latter did not give rise to a continuous spiral. The question of plurality of relapsing fevers was rendered all the more prominent by the demonstration that the spirillum of African tick fever differed from spirillum Obermeieri. Tick fever spirillum formed curves or figures of 8 and had numerous flagella. The spirochætæ probably did not belong to the protozoa (and more especially to the trypanosomes) but were bacteria. There was no definite nucleus, blepharoplast, undulating membrane, or flagellum, structures seen in the trypanosomes. There was evidence of transverse division into cells 8μ long and rapid multiplication ensued in the blood of rats. It could produce active immunity in animals, like the cholera spirillum, unlike protozoa which might exert a preventive but not a germicidal or curative effect. It was indifferent to the presence of air. Rats had been immunised by inoculation and the "recovered" blood possessed two immunity units per cubic centimetre. Blood could be hyper-immunised to contain 500 units or was 250 times more active than "recovered" blood. The infection could be prevented in mice and monkeys also. The immune blood possessed a marked germicidal and agglutinating action *in vitro* and *in vivo*.

In the discussion that ensued the PRESIDENT asked what evidence there was of cure in animals which had been inoculated and Professor NOVY replied that the spirilla disappeared from the blood.

Dr. F. W. MOTT (London) gave a lantern slide demonstration of

The Changes Produced in the Nervous System by Chronic Trypanosome Infections.

The material for examination used was (1) 30 cases of human sleeping sickness, including two Europeans; (2) several cases of trypanosoma Gambiense infection in which there was glandular infection, but in which the nervous system had not yet become involved; (3) tissues of ten monkeys which had been inoculated with trypanosoma Gambiense; (4) nervous tissues of oxen, inoculated with Jinga trypanosome, probably a form of nagana or the tsetse disease; and (5) animals experimentally infected with surra. In the lymph glands, acute, subacute and chronic, and chronic fibrotic changes were observed. In the acute stage there were endothelial cell proliferation of the vessels, lymphocyte proliferation, and nuclear mitosis of the branching retiform cells forming the sustentacular framework of the glands. Similar changes were observed in the perivascular and meningeal lymphatics of the central nervous system. There was chronic inflammatory interstitial change with neuroglia cell proliferation and overgrowth of the central nervous system produced either by the invasion of the cerebro-spinal fluid or by a toxin produced in the lymph glands. Degenerative changes in the leucocytes and plasma cell accumulations could be traced to final disintegration. The demonstration of trypanosomes in sections was extremely difficult. In several thousands of sections of tissues of sleeping sickness not more than half a dozen showed trypanosomes, probably because there was a terminal microbial infection, usually diplostreptococcal. Changes in the central nervous system in dourine or mal de coit were also described, the posterior spinal ganglia being profoundly affected. Orr and Rowes had shown experimentally that poisons were conveyed along the nerves to the posterior roots of the [illegible] cord and it was probable that in mal de coit the lymph glands affected produced toxins which were conveyed along the lymphatics of the pelvic plexus of nerves to the lumbo-sacral ganglia primarily and to all the spinal ganglia eventually.

Professor **WELCH** in discussing the paper said that streptococcic infection caused death in protozoon infections and also in small-pox.

Dr. J. M. **BEATTIE** (Edinburgh) asked whether the lymphocytes in the perivascular lymphocytosis were from the blood or proliferated around the vessels.

Professor **ADAMI** asked whether there were any other nerve diseases showing glia proliferation as in sleeping sickness.

Dr. **MOTT**, in reply, stated that there was a diplostreptococcal infection in 80 per cent. of cases of sleeping sickness bringing about a fatal end. Points of suppuration in the lymph glands were observed. Professor Rose Bradford had shown that the blood in a case of sleeping sickness in University College Hospital was sterile. Lymphocytes might be formed in the lymphatics of the nervous system and glia cell proliferation also occurred in general paralysis, when it was a substitution process.

Professor M. **NICOLLE** and Professor F. **MESNIL** communicated a paper on

The Treatment of Trypanosomiasis by the "Colours of Benzidine."

The therapeutic action of symmetrical diazo compounds was discussed. The benzenic and naphtholenic chains gave rise to inactive derivatives The derivatives which were active *in vivo* against nagana were solutions having a blue, violet, rose or red colour, and were inactive *in vitro*. Asymmetrical diazo compounds offered no advantages over the symmetrical, but rather the reverse, and triazo and polyazo compounds never displayed any curative power even when they contained good lateral chains. The treatment of (experimental) mal de caderas in mice and (experimental) surra in mice and human trypanosomiasis was discussed, and also the treatment of the experimental infection due to trypanosoma dimorphon (mice). The best lateral chain for the four preceeding trypanosomiases was ac. H.; for the first three diazo dichlorobenzidine, for the last paradiamino diphenylurea. For the infection of trypanosoma dimorphon they found the opposite condition. It was safe to hope that a means of distinguishing trypanosomes by the help of a chromo-therapeutic criterion would be arrived at.

Professor **ADAMI** said that the work on chemical constitution and therapeutic action, initiated by Ehrlich, on which Professor Nicolle's contribution was based, was of the highest value.

Professor R. T. **HEWLETT** (London) asked whether nephritis resulted from trypan red.

Professor **HEWLETT** gave an excellent lantern slide demonstration of

A Beri beri-like Disease of the Monkey,

with a description of the pathological histology of beri-beri. Tube casts had been repeatedly found by him at the London School of Tropical Medicine in numbers in the urine in beri-beri, while Dr. Daniels thought that a urinary channel of infection of beri beri was more likely than a fæcal one, though both hypotheses were unlikely.

Dr. **KINYOUN** had observed 20 cases of a beri-beri like disease in monkeys which occupied one cage.

Dr. **BEATTIE** gave a lantern slide demonstration of

A Sporozoon of the Nasal Mucous Membrane, the Rhinosporidium Kinealyi (Minchin).

The sections showed the presence in the mucous membrane of minute cysts with a chitinous envelope. The walls were of varying thickness. The cysts were 0·1 to 0·3 millimetre in diameter and filled with undifferentiated protoplasm; a nucleus and nucleolus could be made out. In others chromatin masses were seen corresponding with the trophozoite stage of the sporozoon. Cysts from six to eight millimetres in diameter were filled with spherical or ovoid bodies, the spore morulæ. Each spore morula had a cell wall. They discharged by rupture or through a pore into the surrounding tissues, forming an abscess, and they would probably be found in the discharges. Finally, granulation tissue invaded the cyst.

Dr. **HEWLETT** communicated a paper by Dr. **DE KORTÉ** on

The Virus of Small-pox and Vaccinia.

Hanging drop preparations of the lymph of the vesicle showed a large number of morphological elements like pus cells, containing highly refractile grains within the cell substance even after 12 months of storage. Large cells were seen with nucleus and karyosome, limited by an ectosarc, the encysted parasite. They were present in fresh active glycerinated calf-lymph; also when it was suspended in saline solution. Morula-like bodies were also present, in addition to spore, sporidium or amœba, encysted parasite, and morula. They were not leucocytes and not epithelial cells.

Dr. J. R. **BALLAH** (Montreal) described his

Experiments with Vaccine Lymph,

his method of obtaining typical vaccine lesions in the animals of the laboratory, the effects of dialysis of vaccine lymph, and the attempted culture of the vaccine organisms *in vitro* and *in vivo* in celloidin capsules. The dialysate was active after 18 hours. The bodies described by Dr. de Korté were to be regarded as albuminoid or lipoid and not even living. A sterile inactive calf serum was added to 2 per cent. broth (+ 1·5) and 20 per cent. hay infusion in equal volume and inoculated with sterile vaccine emulsion (Green's chloroform method), but no growth ensued. With an active vaccine emulsion containing a non-virulent streptococcus in some cases there was a creamy cloud at the top of the fluid which was noteworthy. This appeared to be associated with the production of alkali. It consisted of minute spherical highly refractile bodies varying in size, being just visible. They could not be fixed or stained and inoculation experiments had led to no indubitable results. Possibly they were invisible or ultravisible bacteria.

Dr. **KINYOUN** had seen a vaccine virus which had been stored in the "cold" for five years and which was very active.

Professor **ADAMI** regarded the large spherical bodies described as allied to the lipoid bodies in myelin and as of doubtful significance.

Dr. **BEATTIE** contributed a paper on

The Bacteriology of Rheumatic Fever.

He had examined culturally and by inoculation 12 strains of streptococci and compared them with the micrococcus rheumaticus isolated from three cases of definite acute rheumatism. This organism grew copiously on gelatin and formed much acid, and precipitated the bile salts in McConkey's bile salt lactose broth. The streptococci used as comparison gave no reaction in this medium. On inoculation with streptococcus there was purulent arthritis and once there resulted an endocarditis; pyæmic abscesses in the kidney and spine occurred also. With the micrococcus rheumaticus there was arthritis, non-purulent, in 60 per cent. of cases and in 33 per cent. endocarditis. Dr. Beattie failed to get cultures from blood but the organism could be grown from pieces of the synovial membrane removed from the knee-joint post mortem. The organism differed from streptococcus in the results of injection; it was not an attenuated streptococcus, and in uncomplicated cases of acute rheumatism the organism was not found usually in the blood or in the joint exudates.

Dr. G. A. **CHARLTON** (Regina) said that a series of experiments were undertaken in the pathological laboratory of the McGill University during 1902–03 which in general confirmed the results of Dr. Beattie's work. A micrococcus was isolated from three cases of acute rheumatism. It was similar to a streptococcus morphologically and culturally, but the micrococcus grew more readily. Inoculations resulted in the production of arthritis without pyæmia. Inoculations of strains of streptococcus gave arthritis with pyæmia in most cases. The experiment was not completed or as yet reported.

Professor R. **MUIR** (Glasgow) expressed appreciation of the value of Dr. Beattie's work and asked whether the organism occurred in subacute rheumatic conditions as in nodules. It was possible that the latter were not rheumatic.

LARYNGOLOGY AND OTOLOGY.

Almost the entire contingent of British laryngologists and otologists *en route* for Toronto met in Montreal on Saturday, August 18th. On the following morning they were conducted over the Victoria Hospital by Dr. H. S. Birkett, who has charge of the throat and ear department. The lavish equipment of the building and the facilities for teaching evoked general admiration. By the kindness of Dr. and Mrs. Birkett the members were entertained to luncheon in the Hunt Club and afterwards were shown places of interest in and around Montreal. In the evening a number of the Canadian laryngologists dined with their British *confrères* in the Windsor Hotel. The first opportunity in Toronto afforded to the members and guests of the section of renewing old friendships and making fresh ones was at the successful and largely attended At Home given by Dr. and and Mrs. Gibb Wishart on the Monday evening.

TUESDAY, AUGUST 21ST.

At the opening meeting of the section the PRESIDENT (Dr. J. DUNDAS GRANT, London) made a few introductory remarks, in the course of which he expressed regret that only a comparatively small proportion of the programme was devoted to otology proper. He trusted that the dazzling brilliancy of the results of modern surgical otology might not be allowed to divert their gaze from the minute details of intra-aural technique. The former were answerable for the saving of many lives from danger, but the latter enabled them often to prevent their patients from running into those dangers. Let them remember that the ear was primarily an organ of hearing and cultivate the accuracy and patience in examination and dexterity and delicacy of manipulation upon which their success in relieving their patients and in making their own reputation so much depended.

Discussion on Operations for the Correction of Deviations of the Nasal Septum.

The opening paper was read by Dr. STCLAIR THOMSON (London). The majority of septal deviations, he said, were compounded of deflections and outgrowths of both cartilage and bone. In many cases both nostrils were more or less obstructed. Until recently he knew of no method which could deal with such cases satisfactorily. To produce a large perforation in the septum always appeared to him both inartistic, unsurgical, and in many cases ineffectual, for the obstruction not infrequently ran so far back as to be beyond it. The President had expressed the opinion that it was most undesirable to produce a perforation. To shave off the crest of these deviations seldom left any tangible patency, while those rhinologists who talked of "simply pushing the weakened septum into the median line" could only be admired for their faith in the malleability of the septum, while they were to be congratulated on the tolerance of their patients who would bear the necessary renewal of packings or splints for three weeks afterwards. The rough, unsurgical, and ineffectual use of Adams's forceps and such-like barbarous contrivances, already belonged to the past history of rhinology. For his own part the deviations most requiring treatment had been formerly just those in regard to which he felt most powerless. In some cases he avoided operation on the septum by removing part of the turbinals but in many he felt compelled to advise the patient to tolerate the nasal stenosis as he knew of no satisfactory method of correcting it. A few years ago he would only operate on half a dozen septa in a session, when now he felt justified in operating on 40 or 50. This confidence was begotten of the adoption of the method of excising septal obstructions by the submucous method and he took it that the debate would be largely concerned in discussing the methods, difficulties, advantages, and objections of this operation, while considering simpler measures which might sometimes be used instead of it. His own technique had recently been described in detail in THE LANCET.[1] The first case of this operation shown at the Laryngological Society of London was presented by him on May 6th, 1904. The objections which might be raised would call for discussion. The chief were: (1) the difficulties of the technique; (2) the anæsthesia; (3) hæmorrhage; (4) stitches; (5) the possibility of collapse of the bridge of the nose; (6) danger from subsequent blows on the nose; and (7) unsuitability for children. The technical difficulties disappeared with practice and patience. Hæmorrhage had never given him trouble and he was surprised to read of surgeons who referred to it and the frequent mopping required during the operation. The method of anæsthesia described rendered the operation painless until they came to the removal of bone, which was disagreeable. He had tried and had abandoned the submucous injection of cocaine and adrenalin. His first cases were done under chloroform and he had recently reverted to it for nervous patients requiring an extensive operation. The stitches expedited healing. No collapse had occurred in any of his patients and Freer's experience showed that there was no added risk from subsequent blows on the nose. Under 16 to 18 years of age there was increased difficulty in operating in narrow noses and at an earlier age there was the possibility that it would hinder complete development and the risk of the deviation re-forming if not completely removed. But other surgeons would doubtless give them their experience on these points. The more actual objections which occurred to him were the following: (1) incompleteness of operation; (2) flapping septum; and (3) previous operations. It was the incomplete operation which caused the flapping condition of the septum in which during quick inspiration the fleshy septum was sucked against the outer wall of the narrower side, thus leaving the patient with only one free nostril. If the operation were carried out perfectly both sides would be equally free and the septum, though flaccid, would remain vertical. Previous treatment rendered the operation more difficult; the mucosa might be changed into scar tissue adhering closely to the septum or the two mucous membranes might be united together and the task of separating them became most difficult. The advantages of this operation might be summarised as follows: (1) no general anæsthetic was required; (2) there was no hæmorrhage; (3) the absence of pain and shock; (4) there was no reaction (the post-operative temperature seldom rose above 99° F.); (5) the absence of sepsis with its possible extension to the ear, the sinuses, or the cranial cavity; (6) no splints were required and no plugs after 48 hours; (7) rapid healing, without crust formation; (8) no risk of troublesome adhesions; (9) short after-treatment; (10) speedy establishment of nasal respiration; (11) suitability for all deformities of cartilage or bone in the septum which required treatment; (12) the space gained was not only that which resulted from a vertical septum but the extra room secured by the removal of the cartilage, which was sometimes one-eighth of an inch in thickness; (13) no ciliated epithelium was sacrificed; (14) accuracy of result could be depended on and the prognosis was therefore the more definite; and (15) the improved appearance of the nose externally. He did not wish to magnify their office but it was wrong both to their patients and themselves to minimise, by adopting a half-measure, an operation which with skill and patience could result in so much permanent benefit to those who required it.

Dr. JOHN O ROE (Rochester, New York) read a paper in the course of which he stated that the operations required for the correction of the nasal septum might be divided into those necessary for the putting in proper condition of the nasal passages and those for the straightening of the septum itself. Having taken into consideration the associated abnormalities in the nose it was also necessary to give attention to such conditions as had contributed to cause or were active in maintaining the deviation. It was also important to remove such conditions as would cause either nasal passage to be obstructed when the septum was placed in the middle line. On undertaking the main operation it was especially important carefully to select the operation best suited to the form and conditions of the deflection and the associated conditions of the nasal passages. If there were a marked thickening of the septum the submucous resection was especially called for. In other cases if the set or lower attachment of the septum was at one side of the median line and otherwise generally straight the Watson or Gleason operation was especially adapted. If the deflection were confined to the cartilaginous portion the Asch operation might in some cases be of special service, whereas if the osseous or the osseo-cartilaginous portion were deviated the Roe operation, by the use of fenestrated comminuting forceps, was the one to be selected. No one operation was adequate to all conditions in all cases but each was adapted to a certain variety, and therefore one operation was often a supplement to others. The one operation which would be found more often to meet the requirements of different cases, or to supplement other operations, was the Roe method of fracturing the septum by comminuting forceps. Deviations of the septum, as first and best classified by Jarvis, might be divided into osseous, osseo-cartilaginous, and cartilaginous. The most frequent form was the osseo-cartilaginous occurring in about 60 per cent., while deviations of the cartilaginous portion alone did not exceed 30 per cent. Therefore, other things being equal, the form of operation best adapted for the correction of deviations of the osseo-cartilaginous portion should be twice as often called for as those adapted for the correction of the cartilaginous portion alone. In nearly all instances the bend in the septum found in the osseo-cartilaginous cases took place at or just behind the osseo-cartilaginous junction or

---

[1] THE LANCET, June 30th, 1906, p. 1810

the inferior turbinates would be drawn away from the septum and the latter pulled materially downwards.

Dr. J. A. STUCKY (Lexington, Kentucky) uttered a warning against too great enthusiasm for submucous resection. In the majority of cases of septal deviation the removal of the anterior third of the middle turbinate assisted ventilation and drainage of the upper parts of the nose. For anæsthesia and hæmostasis he recommended a solution containing sodium chloride, five grains; cocaine hydrochlorate, 20 grains; antipyrin, 20 grains; adrenalin solution, two drachms; and water to six ounces.

Dr. H. P. MOSHER (Boston) expected still to use the Gleason operation for hospital work owing to the time required for submucous resection; the latter, however, was the method of choice in private practice. Cargill membrane was better than rubber tissue for preventing adhesions.

Dr. WENDELL C. PHILLIPS (New York) maintained that the guide in deciding as to operation should be symptoms and not the mere presence of a deflection or spur.

Dr. C. G. COAKLEY (New York) had seen straightening of the deflected septum and increased patency of the nasal passages in children with high palates follow the widening of the arch by means of dental splints. The packing should keep the septum in the median plane; too much on one side resulted in a continued deviation, while too little was liable to be followed by the development of a hæmatoma between the layers.

Dr. W. E. CASSELBERRY (Chicago) gave Dr. Freer the credit of originating in America submucous resection of the nasal septum. This operation was, however, not to be preferred in all cases—e.g., in septal deflection with external lateral deformity fracturing operations were more successful, and in young children the Watson-Gleason method was adequate and rapid. To avoid the fragmental dissection of bone far back he sometimes separated the muco-perichondrium on the concave side and then sawed off the projecting bony convexity.

Dr. P. WATSON WILLIAMS (Bristol) had found it advantageous to make a small primary puncture on the concave side well forward in order to avoid perforating while cutting through the cartilage. Through this a long narrow mucoperiosteal elevator was introduced by means of which the cartilage was bared in the region where later it would be incised from the convex side.

The PRESIDENT considered that the discussion showed that there was room for judicious eclecticism in the choice of operation. He usually practised Killian's method but in cases of deflection with a sharp vertical ridge he preferred Freer's L incision. As a rule, he operated on the convex side but when the triangular cartilage was dislocated into one nostril he operated on this side; also, when there was extreme enlargement of the maxillary crest he sometimes selected this side and extended his incision across the floor of the nose so as to allow of the detachment of the mucoperiosteum from below upwards.

Dr. STCLAIR THOMSON and Dr. FREER replied.

Mr. HUGH E. JONES (Liverpool) and Mr. C. THURSTAN HOLLAND (Liverpool) gave a demonstration of

An Exostosis of the Frontal Sinus

and showed a skiagram of the same. The patient, a woman, aged 35 years, had consulted Mr. Jones because of severe pain, obstruction of the right nostril, and protrusion of the right eyeball. The radiogram which was taken with the woman lying face downwards and the plate beneath her face, gave valuable information as to the position and extent of the exostosis. The growth was removed; it measured two and a half by one and a quarter inches.

Dr. MOSHER gave a demonstration of

A Series of Sphenoidal Sinuses,

showing a partial partition on the outer wall. The spur might interfere with drainage and so become of clinical importance.

Dr. SMURTHWAITE read a paper on

Headache: Pathological Conditions of the Middle Turbinal a Causal Factor.

When the bony conformation of the middle turbinal caused it to be close to, or in contact with, the septum a slight degree of turgescence or hypertrophy of the mucous membrane of the opposing surfaces would give rise to pressure. This in some patients was accompanied by one or more of the following symptoms: tightness across the bridge of the nose, a feeling of pressure above the eyes, and pain radiating from the inner canthus and side of the nose towards the intra-orbital or supra-orbital canal, round the eye causing lacrymation or passing up over the forehead and scalp to the occiput. If the nervous supply of the nose were considered it was evident that pressure on the middle turbinal or septum might by transference give rise to pain in other regions supplied by the first and second divisions of the fifth nerve. Several cases were referred to in which relief from symptoms such as those mentioned was obtained by removal of the anterior end of the middle turbinate. It was to this particular region of the nose that Dr. Smurthwaite desired to direct attention as the seat of origin of nasal headaches.

A paper was read by Dr. PERRY G. GOLDSMITH (Belleville, Ontario) on

Some Unusual Cases of Frontal Sinus Suppuration.

The following were the cases detailed. Case 1.—A patient, aged 21 years, complained of post-nasal discharge. Catarrh settled in and about the eye and was accompanied by marked frontal pain. There was enlargement of the anterior end of the middle turbinate and a few polypi bathed in pus were present in the middle meatus. The anterior end of the middle turbinal was removed as a preliminary operation. A few days later the patient informed Dr. Goldsmith that her complaint had been entirely cured but that there was now a disgusting discharge from the nose which she had never had before the operation. The antrum and frontal sinus were both irrigated from the nose for several weeks, when the discharge ceased. Case 2.—A patient, aged 33 years, complained of supra-orbital neuralgia and nasal discharge. Morphine had been given in large doses but without relief. The floor of the left frontal sinus was exceedingly tender but not bulging. This cavity and the left antrum were operated upon and the patient was much better for the next two days. On the third day the temperature rose to 104° F. and was accompanied by marked distress in the head. The packing was removed, which allowed of a free flow of pus and gave immediate ease. Pus was now found to come through a very small opening which led towards the junction of the front part of the forehead and the scalp. Subsequently a large cavity was laid open in this situation. Healing had almost taken place when reinfection occurred due to an acute exacerbation of the disease in the other sinus, a small perforation being present in the septum. The other sinus was then operated upon and both healed promptly. To correct the disfigurement over the sinus first opened a large flap consisting of the entire scar and tissues over the bone was dissected up, the depression was plastered with solid paraffin, and the flap was sutured in place. The cosmetic result was excellent. Case 3.—A patient, aged 64 years, had undergone radical operation on all the sinuses. Twelve hours after the operation on the frontal sinus a severe attack of facial erysipelas set in which infected the antrum, the pharynx, and the larynx, but not the unpacked frontal sinus. Ultimately the patient did fairly well. Case 4.—The patient had frontal sinusitis, orbital phlegmon, and displacement of the eyeball downwards and outwards due to a primary sarcoma in the right nasal fossa. The only complaint was diplopia. The pus in the orbit was evacuated and a large mass of sarcomatous material was removed. The patient was quite comfortable afterwards but died within a year from secondary involvement of the liver. Case 5.—A man, aged 41 years, complained of having caught a very severe cold in the head which caused distress in one of his eyes. Apparently he was suffering from a severe attack of conjunctivitis with iritis. The nasal septum was found to be deflected and on pushing it aside an enlarged middle turbinal was seen to press against the septum. On probing the fronto-nasal duct a small stream of muco-pus escaped. The patient obtained immediate relief and by using menthol inhalations was rapidly well. The ocular condition subsided without further treatment. Concluding, Dr. Goldsmith said that felt burrs of various sizes attached to a dental engine had facilitated greatly the clearing of cavities of their diseased membranes and had assisted in checking hæmorrhage.

Dr. HERBERT TILLEY read a paper on

Some Considerations upon Certain Factors in the Diagnosis and Treatment of Suppurative Lesions in the Nasal Cavities.

With regard to the etiology of suppuration in the maxillary antrum suppuration in that cavity was, he said, due to intranasal or dental infection. It was important to determine which was to blame, for the prognosis and treatment in cases of dental origin were much more favourable. Points of distinction between these two classes of cases were the more frequent presence of hypertrophy of the uncinate process and of polypi in cases in which the sinus had been infected from the nose; when a diseased tooth was the cause of trouble aching in it would often be produced by syringing the antrum. In the matter of diagnosis puncture was most trustworthy but on three occasions there was no return of the injected fluid owing to the valve-like actions of intra-polypi. Pus from the antrum might be situated high anteriorly in the middle meatus owing to a deviation of the septum pressing against the posterior half of the middle turbinate or the presence of a large polypus in the posterior part of the meatus? Alveolar drainage was more likely to be effectual in cases of dental origin when of short duration. Some form of radical operation would be required for the majority of chronic cases of whatever origin and was practically always called for if polypi were present in the middle meatus. He (Dr. Tilley) practised the Caldwell-Luc operation with the following modifications: (1) removal of the whole inner wall and curetting of the lower anterior ethmoidal cells; (2) removal of only as much of the mucous membrane as was diseased; (3) closure of the bucco-antral wound; (4) no packing; and (5) syringing the nasal cavities. The ethmoidal cells were rarely the seat of suppuration except in association with a similar condition in the neighbouring sinuses. When the symptoms pointed to suppuration of 'the frontal sinus the presence or absence of pus could generally be determined by reclusion. In acute suppuration irrigation would hasten cure. In chronic cases it might also be successful if the contour of the sinus were fairly regular and the opening into the nose unobstructed. Pain over the sinus was no proof that disease was located there. The best results in Dr. Tilley's hands had been secured by a simplification of Killian's operation. The details were the same as his with the exception that the floor of the sinus was not removed. The diseased ethmoidal cells were thoroughly curetted through the opening below the bridge of bone and the wound was sutured at the close of the operation. The after-treatment consisted in daily irrigation of the sinus through the nose by way of the large communication made at the time of operation. Osteomyelitis of the frontal bone had been due, in Dr. Tilley's opinion, to the neglect to remove the fronto-ethmoidal and ethmoidal cells at the time of operation, so that the higher sinus had been re-infected and the pus thus retained under tension had invaded the diploë of the frontal bone. Since giving special care to the removal of the ethmoidal cells he had had no cause to fear osteomyelitis. As regarded the sphenoidal sinus in three cases deep-seated pain in an ear which was otherwise normal had been a very definite symptom. Irrigation of the sinus or instillation of a few drops of peroxide of hydrogen would sometimes induce the same symptom. The pulsation of pus in the neighbourhood of the ostium sphenoidale was pathognomonic of suppuration in the sinus. In operating, always more of the wall than seemed necessary at the time of operation should be removed, because of the tendency of the opening to contract. Free drainage was the desideratum. Curetting the interior was not necessary and might be dangerous.

Dr. Freer spoke in defence of the intranasal operation of removal of a large portion of the inner wall of the antrum of Highmore for relief of its chronic suppuration. He had had six consecutive cases of chronic empyema of the antrum with complete recovery in from three to four weeks simply as a result of the free drainage and ventilation of the cavity thus obtained.

Dr. Coakley said that pain in the teeth was almost always complained of while irrigating an acutely inflamed antrum independently of the state of the teeth. He had not removed the floor of the frontal sinus in his latest operations and thereby had saved time during the operation and had not delayed healing. Pain referred to the ear had been common in his cases of acute sphenoiditis.

Dr. F. Fletcher Ingals (Chicago) thought that the frontal sinus could be explored by the probe in 90 per cent. of all cases. When this was possible a free drainage canal could be safely established by the pilot burr which he had recommended. He believed that this operation was as safe as any other on the frontal sinus.

Dr. Mosher had obtained most satisfactory results from Killian's operation in frontal sinus disease. The chief objection to it was the possible deformity. To avoid this they should leave as broad a strip of bone as possible above the rim of the orbit, and the long axis of the opening that was made in the anterior wall should be horizontal and parallel to the orbital margin, not vertical or obliquely vertical.

Dr. Watson Williams emphasised the undesirability of removing normal structures in order to investigate the condition of the sphenoidal sinus. If its ostium could not be inspected he punctured the lower part of the anterior wall with his sphenoidal sinus-cutting forceps. This procedure was free from risk. In antral suppuration the disease was nearly always limited to the inner wall so that removal of this was often sufficient to effect a cure.

Dr. StClair Thomson found last year in Paris that the Caldwell-Luc operation was in many cases giving place to puncture and repeated irrigation. He had no hesitation in doing a submucous resection in the presence of acute or chronic sinusitis. In reference to earache he would shortly publish a paper showing how misleading this symptom was in sphenoidal disease.

Dr. A. Logan Turner (Edinburgh) endorsed the view that when performing a radical operation upon the maxillary sinus the cavity should be opened through the canine fossa, for it was only thus that thorough visual exploration was possible.

Dr. George L. Richards (Fall River, Massachusetts) was of opinion that the large majority of cases of antral suppuration could be treated by puncture through the naso-antral wall. If a large enough opening were made the drainage would be good and many patients could be taught to wash out the sinus through a curved cannula. The question of cure by the intranasal route depended not so much on the duration of the purulent process as on the character of the antral mucosa.

The President was in favour of the treatment of rhinological conditions by rhinological methods but the principle should not be pushed too far. More than once he had wished that he had operated more radically but he was sure that he had in many instances been able by intranasal methods to obviate the necessity for external operations. He exhibited curved bougies for the dilatation of the infundibulum which, combined with the use of Sondermann's suction apparatus, had proved of value in the treatment of frontal sinusitis.

Dr. Goldsmith, in reply, said that the method of exclusion referred to by Dr. Tilley might fail in those cases in which the frontal sinus had emptied itself shortly before examination. They should be sure that sinus disease did not demand attention before they did any major operation on the septum.

Dr. Hanau W. Loeb (St. Louis) read a paper on

A Study of the Anatomy of the Accessory Sinuses of the Nose, based upon Reconstructions of Two Heads.

Reference was made to the method of reconstruction as outlined in a paper read by Dr. Loeb before the American Laryngological, Rhinological, and Otological Society at one of its meetings in June, 1906, by means of which it was possible to reproduce the sinuses in their proper relations, giving an anterior, lateral, and superior view. This made it possible to compare the various sinuses with each other and with those of other heads. The two heads studied were those of two men, one white and the other black, of about the same height, age, and weight. The very great differences which existed between the sinuses themselves and the corresponding ones of the two heads were clearly shown in the reconstructions. In this way only could exact measurements of individual sinuses be ascertained. While no definite conclusion could be drawn from a study of only two heads it was clear that the method furnished the means of more closely studying the sinuses and suggested the likelihood of greater understanding of the varieties, relations, and functions of the sinuses and the causes which led to their irregular distribution. Serial sections of each head were exhibited with drawings from the sections and reconstructions in various planes, showing relations and comparisons of the sinuses.

Dr. Coakley, in a paper on

Skiagraphy as an Aid in the Diagnosis and Treatment of Diseases of the Accessory Sinuses of the Nose,

said that at his request Dr. E. W. Caldwell had skiagraphed about 200 patients suffering from sinus disease. In 46 of these the frontal sinuses were operated upon so that the size and shape of the sinuses could be compared with those conditions as shown in the skiagraphs. It was not very difficult to obtain a plate that would show the presence or absence of the frontal sinuses, their size, and the subsidiary septa. Such plates might suffice to determine beforehand the type of operation best suited for the patient. Dr. Coakley was convinced that an excellent skiagraph could be depended upon to demonstrate even the presence or absence of disease. In a good skiagraph a dark, slightly curved area, almost parallel with the upper border of the orbital arch, had been found to correspond to a recess extending backwards over the roof of the orbit. When a frontal sinus was diseased there were invariably a cloudiness over its site and an indistinctness of its outlines as compared with the healthy sinus. The width of the ethmoidal cell area was easily demonstrated. A side view of the sphenoidal sinus often gave information as to whether the cavity was large or small.

Dr. J. Price-Brown showed a case of Nasal Sarcoma with pathological specimens removed three years ago.

DERMATOLOGY.

Wednesday, August 22nd.

The President (Dr Norman Walker, Edinburgh), in his opening remarks, after thanking the profession in Canada for the honour of being asked to preside and welcoming the visitors, took for his subject

The Place and Position of Dermatology in the Medical Curriculum.

He spoke of certain advantages which the student of the old times had when there was no separation of skin diseases into a department and he was constantly coming across cases all through his course. Now with the modern system of organisation the subject was perhaps better taught though compressed into too short a space. Whilst thinking that systematic lectures had been in the past, and in some subjects still were, overdone, nevertheless he considered that they had their advantages. In the necessary bustle of an out-patients clinique a large number of useful scraps of information might be gleaned but 10 or 12 systematic lectures would enable the student to profit much more from clinical instruction afterwards. As to the period in the curriculum in which a student should be taught dermatology he believed that in the five years' course the fifth summer was the best time. The subject should so occupy a regular place in the curriculum but as to whether it should form part of the degree examination he thought that the Edinburgh system of certificates would suffice. On the question as to what the student should be taught, he was of opinion that the commoner diseases should have prominence, whilst the rarer cases might be dealt with as they turned up. In addition to lectures the "quiz" classes of the Americans were very profitable to the student.

Dr. J. C. Johnston (New York) said that he would have liked more information as to the subjects to be taught and the time to be allotted to dermatology. His opinion was that what the student remembered was what he had learnt face to face with his instructor and that he should be thoroughly "quizzed."

Dr. Gilchrist (Baltimore) insisted on training the student to use his own reasoning powers in the diagnosis of skin conditions. The exercise of common-sense on his part should be encouraged.

Dr. G. H. Fox (New York) mentioned the advisability of teaching clinical diagnosis and leaving dermatological therapeutics to be acquired by the student at a later period. He laid stress upon the cultivation of the student's power of observation and claimed that only by the active use of his eyes in noting clinical peculiarities of common skin diseases, in place of listening passively to what his instructor had to say, could the student become expert in diagnosis.

Professor James Niven Hyde (Chicago) read a paper on

The Influence of Light-Hunger in the Production of Psoriasis.

After speaking of the accumulation of facts, he referred to the statistical frequency as shown in the reports of the American Dermatological Association from the year 1878, when the first return was made, to the year 1903. These reports showed 465,063 cases of diseases of the skin, among which were tabulated 13,979 cases of psoriasis, showing a proportion of about 3 per cent. The percentage of the last seven years ranged pretty regularly from 2·480 to 3·135, showing that the number of persons suffering from psoriasis was on an average nearly the same from year to year. The cities represented in these returns were Boston, Chicago, Montreal, Cleveland, Buffalo, and Detroit among the cities of the north, and New York, Brooklyn, Philadelphia, Baltimore, Washington, St. Louis, Atlanta, Cincinnati, and New Orleans in the nearer south. Of course, these figures did not represent the exact number of persons suffering from psoriasis in the towns named, but only cases falling under the care of experts, where diagnosis was assured and the record trustworthy. After referring to the situation of the lesions and age of incidence, he spoke of the etiology and put down five propositions for discussion.

1. Psoriasis is a disease that never affects the lower animals, whether these be feral or in a state of domestication, for the reason that the integument of such animals is very rarely screened from the light by artificial covering. 2. If psoriasis in man be an expression of resentment on the part of the skin against the partial or total exclusion of light from its artificially covered surfaces, it is clear that the number of persons whose skin is thus abnormally sensitive is relatively small. 3. If psoriasis be a resultant of light-hunger in the skin of certain abnormally sensitive subjects, because of the greater or less degree of exclusion of light resulting from artificial covering of the body, the disorder should be most prevalent and most severe at those seasons of the year and in those countries in which sunlight is least abundant. 4. If psoriasis be a resultant of light-hunger in the skin of certain abnormally sensitive subjects, because of the total or partial exclusion of light from the protected portions of the body, the localisation of the disease in the integument should be largely determined in the regions of such exclusion. 5 If psoriasis be a resultant of light-hunger on the part of the skin of certain individuals, because of the greater or less degree of exclusion of light from the covered portions of the body, the effective treatment of the disease should be by illumination of the regions chiefly involved.

Dr. Duhring did not agree with Professor Hyde as to the cause. He spoke of the importance of internal treatment and discouraged the use of the x rays. In opposing a local cause he said that if there was one disease that was not parasitic it was psoriasis.

Dr. L. D. Bulkley (New York) thought that the eruption was due to metabolic causes; the skin parasites might play a part if the soil was suitable. He believed in prolonged internal treatment as in the case of syphilis. He had seen the lesions disappear under the internal use of large doses of nitric acid. He did not agree as to light-hunger being a cause.

Dr. Ross (Halifax) had had seven cases in hospital at the same time of psoriasis in coal miners; they had not had the condition before taking up that work.

Dr. Fox called attention to the freedom of the negro. He had photographed very many dermatoses but never yet had he obtained a photograph of a marked psoriasis in the negro.

Dr. Corlett (Cleveland) had never seen a case of psoriasis in the negro as an exciting, as distinguished from a predisposing, cause. He believed that light-hunger and local irritation took part, and thought that sunlight caused the eruption to disappear. He had not had marked effects from internal treatment.

Dr. A. R. Robinson (New York) thought that any external agent, toxic or traumatic, might cause psoriasis in a predisposed person.

Dr. Gilchrist believed that the parasitic theory had not been disposed of. The newer discoveries of the spirochætæ and the ultra-microscopic organisms opened up new fields for research.

The President having remarked on the diversity of opinion on the subject,

Professor Hyde, in reply, said that he would have been very much surprised if his paper had not brought out marked differences in the views held by dermatologists on the subject.

Dr. Johnston read a paper on

The Evidence in Favour of an Autotoxic Factor in the Production of Bullous Eruptions.

He mentioned that the basis of all these cases was practically the same and that borderland cases were frequently met with. He did not believe in a tropho-neurotic origin but thought that the symptoms, first general toxic followed later by a secondary anæmia, bespoke an autotoxic origin. A careful investigation into the relative nitrogenous products of the urine was unproductive of result, as they remained fairly constant till suppression began. However, indican was invariably present in bullous eruptions and always indicated autotoxic disturbances. The associated eosinophilia also spoke for such a cause. The effects of treatment also indicated that toxins were concerned. It consisted in saline cathartics, water in large quantities, open-air exercise, the hot-air cabinet with the douche bath, pilocarpine (especially for pruriginous cases when tar also did good), and the limitation of the proteid intake. His conclusions were that these conditions were autotoxic, they originated from proteid metabolism and they exercised a specific action on the vessel walls.

Dr. Bulkley agreed with Dr. Johnston entirely on the question and mentioned that in years past he had seen numerous cases of erythema multiforme, often presenting many bullæ, amongst the immigrants. So frequent were they that they were often alluded to as morbus immigrantium. In them there had been disturbances due to ocean travel—constipation often for a week. In them the disturbance yielded at once to treatment directed to the liver and intestinal relief.

Dr. Gilchrist thought that the question was one of deficient elimination.

Dr. Duhring said that local treatment was only of use for the immediate relief of symptoms. He had seen good results from general treatment somewhat on the lines which Dr. Johnston had laid down. He mentioned the importance of the nervous system in these cases and the difficulty of investigating the rôle played by it.

Professor Hyde spoke of shock as a cause of dermatosis of this kind.

The President having spoken, Dr. Johnston replied.

Professor J. A. Fordyce (New York) gave a lantern demonstration of many interesting cases of skin diseases. The microphotographs were very fine.

Thursday, August 23rd.

A clinical demonstration was given by Dr. Graham Chambers of cases of Ringworm where epilation had been produced by the x rays. He gave two or three exposures of from 15 to 20 minutes. He had not as yet used Sabouraud's pastilles. The cases showed alopecia without any erythema. Cases of pityriasis rubra, molluscum fibrosum, &c., were also shown.—Some excellent photographs were shown by Professor Hyde, including some cases of Blastomycosis.—Dr. Corlett's photographs were also very much praised.

Dr. Robinson read a paper on

Some Errors in the Treatment of Cutaneous Cancer.

The treatment, in his opinion, should be different according to the size, situation, and variety of the lesions. Very small lesions ought to be excised. When situated near the eye or on the nose, where excision if it had to be wide of the mark left bad deformity, the x rays and caustics were to be employed. He advocated scraping in suitable cases and went into details on the treatment suitable to such cases. He pointed out that caustic potash was of diagnostic value in picking out malignant nodules and mentioned beneficial effects from thyroid extract.

In opening the discussion on Dr. Robinson's paper the President spoke of the poor results frequently associated with excision, saying that probably the surgeon was anxious to leave as much of the face as possible. He recommended chromic acid as a useful caustic and one not so painful as some of the other agents mentioned.

Dr. Sherwell recommended the use of arsenic after operation, believing that it had an inhibitory effect on the cancerous diathesis.

Dr. Fox thought that the curette, or even better the dental burr, was of the greatest value preparatory to caustic or the x ray treatment.

Professor Hyde agreed in general with Dr. Robinson's methods. He had not seen any benefit from internal treatment.

Dr. Bulkley stated that alcohol in any form was injurious in epithelioma. Diet should be absolutely vegetarian. Silver nitrate he believed to be harmful in its inefficiency.

Dr. Corlett would like to add electrolysis as a method of dealing with these cases.

Dr. Breakey mentioned pyrogallic acid.

Dr. Gilchrist thought that the x rays were of undoubted value.

Dr. Robinson replied.

Dr. R. W. Taylor (New York) read a paper on

The Evolution of Intraprimary Prodromal Syphilides.

He alluded to the general conception of latency in the evolution of syphilis. He mentioned cases of successive chancres and gave the history of several cases showing a slight traumatism became infected, causing prodromal lesions. He concluded that the whole organism was infected from the beginning and that the process was a rapid one diffused by the blood.

Professor Hyde, Dr. Sherwell, and Dr. Bulkley spoke.

Dr. Gilchrist read clinical notes on a case of

Pityriasis Rubra

proceeding to gangrene of the extremities, a finger of the right hand and the whole of the left foot. The patient unfortunately left the hospital in the same chronic condition. She had been in hospital for some time and was in the same state when last seen. Examinations of the blood, urine, &c., all gave negative results as to any indication of the cause of the disease.

Professor Hyde spoke of weak solutions of carbolic acid leading to gangrene.

Dr. Corlett read a paper on

Dermatitis Vegetans

and showed photographs illustrating a case. He discussed the nature and etiology of the affection.

Dr. Wende (Buffalo) said that he had had several cases of this disease.

Friday, August 24th.

The proceedings were opened by a demonstration of cases, one of which was a case of pemphigus foliaceus of four years' duration. Another interesting case in a man, aged 49 years, was shown. The opinion generally held was that it was an example of pemphigus vegetans.

Dr. Bulkley read a paper on

The Wrong and Right Use of Milk in the Treatment of Skin Diseases.

Milk he considered to be a natural food and should be suitable to all. Laboratory theories on the subject would probably require modification. He believed that milk was capable of absorption without preliminary caseation and digestion. Administration should be at the time of alkaline digestion and away from any time of other food ingestion. If given so it was beneficial in acne when otherwise it would not be well borne. Cases of eczema and urticaria were also improved by this diet.

Dr. Duhring also spoke.

Dr. Graham Chambers introduced a discussion on

The Etiology of Eczema.

He reviewed the diversity of opinion on the subject and commented on its frequent association with asthma. He discussed the views of Dr. I. Walker Hall of Manchester on infantile eczema. Dr. Chambers considered it to be a disorder due to malnutrition.

The President laid stress upon the importance of external irritation as a cause, mentioning the dermatitis which some suffered from when exposed to primula obconica and other plants.

Dr. Bulkley supported Dr. Chambers's view as to an internal cause.

Dr. Duhring considered that the term "eczema" was used much too widely. He would distinguish eczema from dermatitis.

Dr. Sherwell believed in the constitutional nature of the disorder.

Dr. Guthrie Rankin (London) read a paper on

Blood Examinations as an Indication for Treatment in Certain Skin Affections.

He had used Wright's methods and considered that they gave clear and definite information as to the causes and treatment.

The President, Dr. Gilchrist, and Dr. Duhring having spoken on the subject, the proceedings of the Section terminated.

PEDIATRICS.

Tuesday, August 21st.

After some introductory remarks by the President, Dr. George Alexander Sutherland (London),

Dr. Robert W. Lovett (Boston) read a paper on

Osteogenesis Imperfecta,

an essentially congenital condition characterised by the occurrence of multiple fractures during intra-uterine life or in infancy. The long bones were chiefly affected and as many as 113 fractures had been recorded in a newly born child in one case. When the first fracture appeared after the age of three or four years the total number of fractures experienced was not so great as when they commenced at an earlier age. The history of a case attended by Dr. Lovett was given in which ten partial or complete fractures occurred up to the age of five months. The child died at the age of ten months from a general affection. Pathological examination showed very marked changes in the bones, the process of bone formation everywhere being checked and of an abnormal kind. The fibrous layer of periosteum was thicker than usual and instead of a continuous layer of normal bone the periosteum formed separate plates of non-laminated or imperfectly laminated dense bone in which were oval instead of stellate bone cells and large marrow spaces instead of Haversian canals. An interesting series of micro-photographs illustrating the pathological changes was exhibited.

Dr. HENRY ASHBY (Manchester) considered that Dr. Lovett's case was a noteworthy contribution to the subject of this disease. He did not think that this class of case was always fatal but that there was a class of apparently healthy infants whose bones fractured with very slight violence; the bones united readily and finally complete recovery occurred.

Dr. W. EWART (London) read a paper on

Abdominal Atony in Rickets.

As the medicinal treatment for this affection he recommended small doses of castor oil, to be given daily, and considerable doses of hypophosphites. He particularly advised the external application of massage, friction, and electricity and exhibited two elastic abdominal belts which he had devised and found most useful in treatment as they acted as a stimulus to respiration, supplied a hypogastric support, and tended to prevent gastric dilatation. The essential points of these belts were that the fabric was india-rubber and the usual elastic webbing was replaced by india-rubber cords.

The PRESIDENT said that he considered the abdominal atony to be secondary to gastric dilatation. He approved of the belt treatment as a respiratory stimulant and also agreed as to giving castor oil but did not approve of giving such large doses of hypophosphites.

Dr. EDMUND CAUTLEY (London) considered that the use of an abdominal belt would only aggravate the condition by lessening the activity of the abdominal muscles.

Dr. C. J. KAUFFMANN (Birmingham) recommended urotropin as an intestinal antiseptic in these cases.

Dr. EWART, in reply, protested against the tendency to condemn remedies *a priori* without trying them and once more urged a trial of elastic pressure by the abdominal belt.

Dr. ASHBY read a paper on

The Medical Aspect of Pneumococcal Infection.

He emphasised the importance of a suitable condition of soil for the implantation of the pneumococcus and considered that if the discovery of this organism had not yet led to any very practical results as regards serum treatment it had taught them the great value to individual patients of fresh air. This had been well exemplified by the success attending the treatment of measles and whooping-cough complicated by pneumonia in open-air shelters. He pointed out that the pneumococcus frequently gave rise to meningitis and described some typical cases of pneumococcal meningitis. He considered that a greater care of infant life, better nutrition, pure air, a levelling down of the slums, and a levelling up of the slum-mother would do more than aught else to lower the mortality from pneumococcal infection.

Dr. STUART MCDONALD (Edinburgh) spoke about the pathological aspect of pneumococcal infection and pointed out that the pneumococcus was the most potent disease-producing germ in children next to the tubercle bacillus. There was a greater tendency to general septicæmia from pneumococcal infection in children than in adults. Any important advance in treatment was likely to be found in the production of a vaccine and not of a curative serum.

Remarks were made by the PRESIDENT, Dr. JACOBI (New York), Dr. MACHELL (Toronto), Dr. BIER, and Dr. CAUTLEY. All deprecated excessive treatment in pneumonia and Dr. Jacobi pointed out that in his experience the prognosis of pneumococcal meningitis was not so severe as had been stated by some authorities.

WEDNESDAY, AUGUST 22ND.

Dr. C. L. STARR (Toronto) read a paper on

The Treatment of Tuberculous Abscess.

He reviewed the various methods of treatment of this affection: 1. The expectant method, the patient being put in the recumbent position and the affected limb firmly fixed. In favourable cases absorption might occur. 2. Aspiratio which he considered had the advantage of easy applicabil but did not remove the focus of disease in the abscess wa 3. Injection of germicidal agents which he mentioned or to condemn. 4. Excision of the entire sac as advocated Watson Cheyne. This he considered an ideal method treatment in the limited number of cases to which it w applicable. 5. Incision and drainage. He entered a hear protest against this common method of treatment of th affection which was advocated in most text-books and ev in recent works on orthopædic surgery and diseases of bon and joints. He considered that this treatment invariab resulted in sepsis and frequently endangered the life of t patient. 6. The method he adopted and recommended w that of incision, evacuation of the contents, curetting of th wall, and closure of the wound. He had presented a repo of 25 cases treated by this method at the Americ Orthopædic Association in 1901, but it received a go deal of unfavourable criticism. He now reported 30 add tional cases treated by this method which he consider gave better results than any other form of treatment. Th abscess should be incised freely, the contents evacuated, th wall wiped with 10 per cent. iodoform gauze aided by th curette, the cavity cleaned as perfectly as possible, th wound closed with deep sutures, and firm pressure by ant septic dressings applied. Swabbing the abscess cavity wit pure carbolic acid and filling it with iodoform emulsion, a at first recommended, had now been discontinued.

Remarks were made by Dr. RIDDELL and Dr. RALP VINCENT (London), the latter of whom thoroughly agree in Dr. Starr's condemnation of the method of treating thes abscesses by incision and drainage.

Dr. BLACKADER (Montreal) read a paper on

Rheumatism in Children.

He emphasised the fact that in childhood purely arthriti manifestations of rheumatism might frequently be wantin and might be replaced by such ailments as tonsillitis, chorea pleurisy, muscular pain, exudative erythema, and epistaxis According to the statistics of the investigating committee o the Association, tonsillitis was associated with rheumatism i 25 per cent. of all cases, while the records of the Vanderbil Clinic of New York gave the proportion of cases of tonsillitis in rheumatism as 35 per cent. Recent inoculation experiments by Fritz Meyer in Germany and Frissell of New York pointed to the fact that the tonsils were the pathway for the entrance of the rheumatic organism. Hence careful attention to the condition of the tonsils was especially demanded in all children with a rheumatic tendency. All American authorities were agreed that subcutaneous fibrous nodules, so frequently observed in England in cases of rheumatism, were of rare development in America. With regard to treatment, Dr. Blackader laid chief stress on prophylaxis, correcting tendencies to anæmia, and avoiding over-fatigue. Rest in bed he considered most important. Frequent examinations of the cardiac area should be made, though in his experience severe cases of carditis were not so common in America as in England. He considered that the prognosis of rheumatic heart affections was better in children than in adults.

The following took part in the subsequent discussion: Dr. MCCRAE, Dr. DUKE, Dr. ASHBY, Dr. BAINES, Dr. KERLEY, Dr. HAND, Dr. LA FÉBRA, Dr. CAUTLEY, Dr. KAUFFMANN, and the PRESIDENT. There was a general consensus of opinion that subcutaneous fibrous nodules were not such frequent rheumatic manifestations in America as in England and also that their prognostic significance was not so grave as it used to be considered. The American speakers did not seem to depend so much on treatment by salicylates as we are accustomed to in Great Britain.

The last business of the day's proceedings was a discussion on

Congenital Laryngeal Stridor,

held conjointly with the Section of Laryngology. This was introduced by Dr. A. LOGAN TURNER (Edinburgh). After describing the symptoms of a typical case, he reviewed the various theories which have been advanced to account for the phenomena: (1) reflex laryngeal irritation produced by the presence of adenoids (Eustace Smith); (2) compression of the trachea by an enlarged thymus gland (Avellis); (3) congenital malformation of the upper aperture of the larynx (Lees, Sutherland and Lack, and others); and (4) an ill-coördinated spasmodic action of the respiratory muscles inducing an exaggeration of the normal infantile type of larynx

—an acquired deformity. This was the view which he himself held in common with Dr. John Thomson. They had together examined a number of larynges from stillborn infants and from children up to the tenth year of life, and showed by simple experiments that the malformation which had been regarded by some writers as a congenital one could really be produced by spasmodic inspiratory efforts acting on the soft collapsible structures of the infantile larynx. The crowing sound was produced mainly at the abnormally approximated ary-epiglottic folds. Dr. Logan Turner illustrated his subject by a series of interesting photographs thrown on a screen and by several stereoscopic views.

Dr. Ashby described a case in which congenital laryngeal stridor was associated with an occipital meningocele. The child died at the age of nine weeks and at the post-mortem examination no adenoid overgrowths or enlargement of the thymus were found, and the larynx did not differ in any respect from that of an infant of the same age unaffected with stridor. He was inclined to the belief that in the cases of congenital stridor which he had watched the efficient cause was a neurosis, the result of a disturbed coördination.

Dr. Cautley showed the larynx of a child who had suffered from laryngeal stridor. He did not believe that the condition was due to a neurosis but supported the view that it was due to a congenital malformation of the upper laryngeal orifice.

Dr. Jacobi said that they were too much given to building up theories on a single case and that in his opinion the condition was due to a variety of causes.

Dr. A. Brown Kelly (Glasgow) said that the stridor was not due to vibration of the ary-epiglottic folds but to vibration of a flap of mucous membrane on the summit of each arytenoid.

Dr. Sutherland supported the view that the condition was primary and congenital.

Dr. F. Dundas Grant said he had only had a post-mortem examination in one case, when the stridor was caused by an elongated epiglottis drawn down over the larynx.

Remarks were also made by Dr. Wishart (Toronto), Professor Ingals, Dr. Hudson McEwen, Dr. Porcher (Charleston), and Dr. Chevalier Jackson.

THURSDAY, AUGUST 23RD.

Dr. Kesley (New York) introduced a discussion upon

Entero-colitis in Infants

by the reading of a paper on the Prevention of Acute Intestinal Diseases in Summer. In his opinion the chief etiological factors of the disease were climate and environment, a disordered gastro-intestinal tract, and improper food. He emphasised the importance of education in the prophylaxis of the disease. Mothers should be taught how to feed their infants before the hot weather came on, farmers should be educated as to the supreme importance of cleanliness in the dairy, medical men should be educated in the proper methods of infant dietary, and the consumers should be taught that pure milk could not be obtained in towns for less than 12 to 15 cents a quart. He considered that the mortality from infantile diarrhœa would continue until municipalities established milk depôts at a financial loss and appointed not visiting physicians or trained nurses but women who could instruct mothers how to feed and care for their children.

Dr. J. L. Morse (Boston) followed with a paper on

The Dietetic Treatment of Entero-colitis.

He said that the object to be aimed at was such an arrangement of the food as would starve the bacteria without starving the body. At the commencement of the treatment food should be entirely stopped. Children could bear the withdrawal of food for from 24 to 72 hours or even for longer periods, provided they were given as much water as they would normally get in the food. If they would not take it by the mouth it should be given with a tube or per rectum, and if not retained by the stomach or intestine it should be administered subcutaneously in the form of normal saline solution. When food could be resumed by the mouth he gave either whey or pasteurised buttermilk, which might be strengthened by the addition of cream as the patient improved.

Dr. La Fétra (New York), in discussing the medicinal aspect of treatment, laid stress in the first place on hygienic measures, especially proper clothing and good air. The chief indications for treatment were: (1) to keep up the nourishment of the system without adding to the intestinal irritation; (2) elimination, by the use especially of alkaline sulphates, Glauber's salt being most useful in children over nine months of age (ten grains every hour or half hour for four or five doses); in younger infants or when the patient was very depressed calomel or castor oil should be given, together with colon irrigation or lavage of the stomach; and (3) to allay the inflammation. He considered that atropine ($\frac{1}{1000}$th of a grain given hypodermically every two hours) was an excellent remedy and also that opium was not so much used as it deserved to be. He was accustomed to give it when the temperature was normal and there was no marked toxæmia but yet the diarrhœa did not yield to other remedies. He gave one-fifth of a grain of Dover's powder or five minims of paregoric after each loose stool.

Dr. Shaw (Montreal) read a paper on

A Study of the Absorption of Fat in Infants.

He fully described his methods and illustrated his paper by several charts and diagrams. He said that the irregularity in the quantity of volatile fatty acids found in the fæces during his observations showed that they were not dependent upon any one constituent of the food. In the normal infant the amount of neutral fat in the fæces was very small—0·107 gramme a day in the breast-fed infant and 0·179 gramme in the bottle-fed infant. Most of this was fat that had escaped the action of the fat-splitting enzymes by being entangled in proteid curds. About 4 per cent. of the fat ingested appeared in the fæces in nurslings and 5 per cent. in bottle-fed infants. The fat found in the fæces was to a great extent fat that had escaped digestion. The fatty compounds in the fæces existed as neutral fat, fatty acids, and soaps. The fatty acids were usually in excess of the other two constituents. The soaps were increased in artificially fed infants, in infants with a low percentage of fat in the food, and in infants with *diarrhœa*.

Dr. Ralph Vincent read a paper on

The Milk Laboratory in Relation to Medicine.

He gave details as to the establishment of the Walker-Gordon milk laboratories and outlined the treatment of gastro-intestinal disorders in children at the Infants' Hospital, London. In that institution drugs were almost entirely discarded and such disorders were treated by modification of milk in the diet. He was of opinion that an infant could be reared upon properly modified cow's milk just as well as upon breast milk. He was particularly severe upon the host of artificial infants' foods, the only saving clause with most of them being that after a certain time the infant refused to persist with them and, with a sense of the fitness of things remarkable at an early age, consistently vomited them. He considered that the use or tolerance of patent foods for young infants by medical men was most damaging to the reputation and scientific standing of the profession. The educational influence of laboratory methods on mothers and nurses was very good. The care exercised by the laboratory impressed them with the importance of the subject and encouraged them to understand the real meaning of infantile nutrition.

Dr. Ashby said that the establishment of the Walker-Gordon milk laboratory was almost entirely due to Dr. Vincent's enthusiasm.

Dr. Blackader said that in his opinion much harm was done by taking infants out for what was known as a day's outing when all food required for the day was taken with them and on account of the increased liability to fermentation of the food gastro-intestinal disorders were likely to be produced in this way. He thought that the dread of giving opium in such disorders was carried too far.

Dr. Putnam, Dr. Riddell, Dr. Benedict, and Dr. Knox also joined in the discussion.

Dr. Morse said that he did not much approve of milk laboratories but that if he could get pure clean milk he would as soon have it modified at home. He entirely disagreed with Dr. Vincent's remarks about breast feeding, the importance of which he strongly emphasised.

FRIDAY, AUGUST 24TH.

The closing session of this Section was chiefly occupied with an interesting discussion on

Congenital Pyloric Stenosis.

This was opened by Dr. Edmund Cautley, who dealt with the medical aspect of the affection. He directed attention mainly to two *groups of cases*: 1. Functional pyloric spasm, the main feature of which was severe and continued vomiting without any gastric dilatation or pyloric *tumour*. *Cases of this kind were extremely likely to give* rise to an erroneous diagnosis of congenital hypertrophic stenosis. They usually recovered on a diet of whey with small doses of cocaine internally. 2. Congenital hypertrophic stenosis. He had had 16 cases under his own observation, on the course and results of which his conclusions were mainly based. Almost all occurred during the *first three months* of life, generally during the first month, indicating that the affection was one of very early life, that it did not develop after this age, and was probably congenital in origin. Lack of appetite might be the first symptom but was often overlooked. Vomiting was the chief characteristic; in typical cases two or more meals were kept down and then the whole lot was brought up forcibly and violently ejected, sometimes to a distance of three feet. There was some pain but no nausea and food could be taken almost immediately after. Constipation was usually present; the child wasted progressively, sometimes with extraordinary rapidity, the temperature was *subnormal*, and the pulse small, frequent, and weak, the general appearance being one of whining lethargy, with half-open eyes. The physical signs were visible peristalsis, *dilatation of the stomach*, and a tumour in the region of the pylorus, half an inch to the right of, and three-quarters of an inch above, the umbilicus, of about the size and shape of a filbert. The pathological condition in this affection was a *true hyperplasia, an overgrowth of the* circular muscular fibres of the pylorus. Possibly the condition represented an atavistic tendency, a reversion to an *earlier type of pyloric development analogous to the* "gastric mill" of crustacea and edentata and the "gizzard" of birds. Though he admitted that spasm might exaggerate the obstruction, yet he maintained that it was not the prime cause, and he was not a believer in the "spasm" theory. The prognosis in these cases was extremely bad if treatment was purely medical, even when the obstruction was incomplete. With regard *to treatment in a doubtful case the food should* be as simple as possible, non-irritant, and given in small quantities at a time. In addition, $\frac{1}{100}$th of a grain of cocaine or a *minute dose of opium, say a quarter of a minim of the* tincture, should be given every hour. If there was no improvement in a few days the stomach should be washed out daily with a weak alkaline solution. When the diagnosis was certain operation should be undertaken at once. He regarded the stretching operation as unscientific and dangerous and considered that pyloroplasty afforded the best results. A good *anæsthetist was essential*. Immediately after the operation a rectal feed should be given, one ounce each of peptonised milk and water, with 20 drops of brandy if needed. This should be repeated every four hours for two days every six hours for two days, then twice a day for two days. A teaspoonful of hot water should be given by the mouth every quarter of an hour for six or 12 hours, after that a similar quantity of whey. Subsequently the diet should be slowly increased to two teaspoonfuls every quarter of an hour, half an ounce every half hour, one ounce every hour; and finally two ounces every two hours; *then gradually strengthened by* the addition of cream or replaced by peptonised milk or milk and water, until the child was on an ordinary diet.

Mr. HAROLD J. STILES (Edinburgh) *treated the subject* from the surgical aspect. He reviewed in detail both the normal and morbid anatomy of the parts and said that while he could fully corroborate Professor Cunningham's statement that in post-mortem specimens the normal pyloric canal of the child was usually in the contracted or systolic condition described by Pfaundler, yet he *had no hesitation* in stating that, without exception, all the cases of infantile pyloric stenosis which he had operated on during life, or examined after death, showed an *amount of muscular* thickening of the pyloric canal two or even three times greater than any normal pylorus that he had ever come across. The main fact which concerned the surgeon was that he *had to* do with an organic but purely muscular hypertrophy of the pyloric canal, associated with excessive tonic contraction, aggravated no doubt by more or less spasm, but it was difficult to say whether the latter was cause or effect. With regard to treatment, it was important that medical treatment should not be too long persisted in but that the patients should be submitted to early operation. He detailed the various steps of the operation, laying particular stress on the following points. Shortly before the operation the stomach should be washed out and an enema of one or two ounces of saline solution and from 10 to 20 drops of brandy given. In many cases it was advisable to introduce saline solution subcutaneously *into* both sides of the chest. A good anæsthetist was essential; the anæsthetic should be *chloroform* and ether followed by ether alone. On no account *should* an antiseptic (especially carbolic acid) poultice be applied to the abdomen *even for an hour or two before the* operation, as it had been shown by Dr. Kruger that a lethal dose of the drug might very easily be absorbed by the skin in that time. *The skin incision should not* be more than two inches in length, having its centre midway between the ensiform cartilage and the umbilicus. Great care in the *closure of the abdominal* wound was most important in order to avoid the risk of the wound *bursting open after it* had firmly healed or the occurrence of ventral hernia. The abdominal wall was so thin that suturing in layers was out of the question. *Interrupted sutures of fishing gut should be* used; they should be passed through the whole thickness of the abdominal wall and one extremity of each threaded with a *piece of thin rubber tubing* half an inch in length and tied in such a way that the portion of the loop which overlay the skin was surrounded by the tubing in order to prevent the suture cutting its way through the skin. Mr. Stiles described the various operations which had been undertaken for congenital pyloric stenosis—viz., (1) *Loreta's Divulsion* operation, the great point in which proceeding was *that it should be done gradually yet thoroughly*. Out of a total of 29 divulsions which he had been able to collect there had been 15 recoveries—a little over 50 per cent. (2) *Gastro-enterostomy*, in which he recommended the posterior operation. He had collected 37 cases, with 16 recoveries (43·2 per cent.). (3) *Pylorectomy*. He had only had one case, which died from shock, and he considered it an unnecessarily severe procedure. (4) *Pyloroplasty*. He had only performed it once, unsuccessfully, but it was the operation performed and recommended by Mr. Clinton Dent who had operated in Dr. Cautley's cases. He had five *recoveries* out of 11 cases (45·4 per cent.). There were two other operative procedures employed by Mr. Nicoll—viz., a combination of divulsion with gastro-enterostomy, and a modified *form of pyloroplasty*, which he described in the author's words. Five out of six cases operated on by this method recovered. It seemed to him that cases of pyloric stenosis should be *divided into* two distinct groups—*viz*., (1) the purely spasmodic, without any hypertrophy, which might be expected to get well under dietetic and medical treatment, and (2) the true congenital hypertrophic, *which* must assuredly die unless surgical treatment were resorted to. He believed that there was also an intermediate group, in which the hypertrophy *although* present was less marked. It was these cases which had led to the confusion and difference of opinion regarding the pathology and treatment of the disease. He would *advise* a diagnostic incision in all cases in which the diagnosis was doubtful and medical treatment afforded no relief. If there appeared to be distinct though not marked hypertrophy and the infant was very young and weakly, he would be contented with divulsion. When there was marked hypertrophy and the patient's general condition was satisfactory the choice lay between pyloroplasty and gastro-enterostomy and the surgeon would no doubt choose the procedure of which he had had most experience.

In the discussion which followed Dr. PUTNAM (Boston) *gave* details of a case which he had successfully treated by forcible dilatation with a uterine dilator. The tissues torn by the rupture had been closed by sutures.

Dr. ROBERT HUTCHISON (London) expressed profound disagreement with the views of Dr. Cautley and Mr. Stiles. During the last two years he had seen eight well-marked *cases* of the disease, all of which recovered under medical treatment. So long as such a series of cases could be produced operation could never be *regarded as the best treatment* in the early stage.

Dr. ASHBY mentioned two cases in which post-mortem examinations had been held and *showed a specimen*. He did not feel justified in urging operation in these cases though he might recommend it.

Dr. KERLEY said that he was particularly interested in Dr. Hutchison's remarks. He had lately had a case presenting all the classical signs of pyloric stenosis which recovered completely with small quantities of breast milk and daily lavage. If no improvement occurred under suitable medical treatment he would *recommend an exploratory* operation.

Dr. PRIMROSE (Toronto) suggested that dilatation of the stomach was the primary factor and *that the pyloric stenosis* was caused by the difficulty in overcoming the mechanica effects of dilatation. He thought that some surgical procedure might be devised in order to diminish the size of the dilated stomach and avoid the risks of gastro-enterostomy or pyloroplasty.

Dr. VINCENT said that, in his opinion, the presence of a palpable tumour was an essential point in the diagnosis of these cases. He did not agree with Dr. Hutchison's views and could not accept the diagnosis of stenosis in the cases which he had mentioned.

Dr. MACHELL said that cases of congenital pyloric stenosis were not common in Toronto This was evidenced by the fact that up to the present no case had been admitted as such into the Hospital for Sick Children, Toronto. The same applied to the Infants' Home, where many of the infants were nursed and looked after from birth up to two years of age.

Remarks were also made by Dr PORTER (San Francisco) and by the PRESIDENT, and Dr. CAUTLEY and Mr. STILES briefly replied.

The business of the section concluded with a paper by Dr. ALBERT E VIPOND (Montreal) on

The Glandular System in Infectious Diseases

He discussed in detail the significance of enlargement of the lymphatic glands in the various infectious diseases and pointed out that as this enlargement appeared some days before the development of the diseases it formed a valuable aid to diagnosis and enabled isolation to be carried out more

passport to the wise men assembled in solemn conclave at Apothecaries' Hall. This body of self-elected Examiners (being a century behind the better educated general practitioner in literary and professional acquirements) have scarcely intellect sufficient to enable them to undertake an adequate professional examination. Creatures, therefore, of this mediocre description, *pass* as a *matter of course;* and apothecary being now legally tacked to his name, surgeon also is immediately appended, and then the bluster and pomp of a new and important office is observed to commence.

A fellow of this origin and character (called, perhaps, in the absence of a better-informed practitioner, to a case strictly under his neighbour's care) commences with denouncing, in a bold and clamorous manner the measures which have been pursued, and promises to cure the patient in quick time. Nature kindly seconds his impudent pretensions, and this daring charlatan, in spite of his own mischievous principles, (if, indeed, he have any to direct his treatment,) exults in finding, by an unexpected and propitious *turn up*, he has out-witted his less arrogant and pretending rival, and obtained credit for superior discernment in that circle to which he has been, by mere accident, introduced.

THE LANCET.

LONDON: SATURDAY, SEPTEMBER 29, 1906.

What is Specialism?

OUR correspondence columns have lately borne abundant testimony to the interest taken by the medical profession in some of the modern developments of what is vaguely called "specialism," and in questions connected with the methods by which this "specialism," in some one or other of its varieties, may be embraced as a declared and legitimate limitation of the intended field of action of a practitioner, carrying with it, as it unquestionably does, a definite claim to the possession of more than ordinary skill and knowledge concerning the subjects covered by its title. Some of our correspondents have enlarged upon the difficulty of establishing a "special" practice, and one has gone so far as to describe a large proportion of "specialists" as being, at least for a time, persons who are ignorant of everything in general, the so-called "specialism" not excepted, until they have had opportunities of learning something about the particular branch of practice to which they propose to devote themselves. To put the matter quite simply, we believe that much of what is called specialism is a consequence of demands created by the ignorance of the public rather than of any legitimate division of labour in the profession; and that it behoves both the leaders of medical opinion and the guides in whom the public repose most confidence to contend, so far as they are able, both against the artificial multiplication of so-called "specialisms" and against their being used as stepping stones to exceptional practice.

"Specialisms" are roughly of two kinds, those for the practise of which some form of knowledge is required which has no applicability to the diseases of other portions of the body, and those which are mere limitations, and in which the practitioner applies the ordinary principles of medicine, of surgery, or of therapeutics, within a restricted area. The former kind includes ophthalmology and otology; the latter includes certain natural divisions, such as gynæcology and dermatology, but these may be indefinitely and undesirably increased in number by the caprice of any practitioner who chooses to say that he will confine his practice to certain conditions of the system or to certain structures or regions of the body. Men who commence practice with no intention of becoming specialists may yet be guided into some particular department almost by accident; and as they acquire distinction in it may find that their services are but little sought after in other directions. In such cases they lapse into specialism gradually, and sometimes unwillingly, and it may be long before they lose either the possession of general professional knowledge or the desire to exercise it. For obvious reasons we will not speak of living persons, but we need not go far back in medical history to find good illustrations of our meaning, drawing those illustrations from ophthalmology, the best example of definite specialism. The late Sir WILLIAM BOWMAN was surgeon to King's College Hospital and teacher of physiology in the school. His attention was first directed to practical ophthalmology when doing his admirable work as a physiologist on the minute anatomy of the eye, and on the early death of Mr. DALRYMPLE he stood forth as his obvious successor. The late Mr. CRITCHETT, again, had become senior assistant surgeon to the London Hospital before the amount of eye practice coming to him by reason of his connexion with the Royal London Ophthalmic Hospital induced him to abandon general surgery, in which he had already made his mark as an accomplished diagnostician and a brilliant operator. These gentlemen were "specialists" of a perfectly legitimate kind. They were surgeons completely equipped with professional skill and knowledge, and they were induced by circumstances to confine their activities within the limited field which they cultivated with untiring assiduity and to the great advantage of the public. Their patients would not have derived any benefit if Sir WILLIAM BOWMAN or Mr. CRITCHETT had continued to make occasional excursions into the fields of lithotomy or herniotomy but undoubtedly derived great benefit from the knowledge of the general principles of surgery and of therapeutics possessed by the famous ophthalmologists, and from their ready appreciation of the influence of constitutional upon local conditions. We hold that no man should voluntarily limit himself to a single branch of professional activity until he has so far gained experience over the whole field as to be able fully to appreciate the influence which may be exerted by such conditions as constitutional syphilis or a gouty diathesis over the changes produced by disease or treatment within the boundaries which he specially affects. If this opinion be well founded, it follows that too early a limitation of the field of practice is more likely to be injurious than to be useful and that it is, generally speaking, an error of judgment for a young man to start in life with the idea of becoming a specialist. If he does so, he should at least realise the necessity of gaining wide experience and of keeping himself abreast of progress in all departments of the profession.

It is not the least of the mischiefs of specialism that, by marking off certain areas as the property of a few individuals, it has some tendency to induce general practitioners to neglect these areas and to be contentedly less conversant than they ought to be with the matters contained within their boundaries. If we are to have new limitations set up (and the tendency of the present day seems to be in that direction), if we are to have a specialist for dyspepsia, and specialist for obesity, and a specialist for the liver, and a a specialist for gout, and a specialist for the heart, what will be left about which the general practitioner may be expected to possess ample knowledge, and where and by what means will it be possible to train up such men as JENNER and GULL and ANDREW CLARK for the benefit of future generations? The whole question is, we think, one concerning which the profession should strive to educate the public. The human body does not admit of being parcelled out ir diseases of the great toe, is not likely to justify the confidence for which he asks, unless he is thoroughly conversant with the ways and directions in which the state of the great toe may be influenced by the general bodily health, or may exert influence upon it in turn. With regard to those of our correspondents who inquire as to the methods by which they may legitimately make known to what malady or to what portion of the body their energies are to be devoted, or even the fact that they do propose to limit their activities in such a manner, we fear we have no suggestion that would be of practical value. The main objection to all the devices which we have ever seen for informing the public of an intention to specialise is that they savour of trade and of trade competitions. It is incumbent on all who practise medicine to emphasise the fact that our calling is not a mere trade. Its members must merit and win the esteem and confidence of the public as a profession of honourable gentlemen, scrupulously excluding from their ranks everything that savours of pretentiousness and self-assertion. We cannot run with the hare and hunt with the hounds. We must stand absolutely aloof from the devices of competition or we must submit to be submerged by them.

◆

The Perils of Vagrancy.

JUST as an organism cannot be called healthy if any part of it be the seat of disease, so the body politic is defective if any class or section of it be living in unsatisfactory conditions. Much attention has recently been directed to the increase which has taken place in the number of social outcasts, collectively designated as tramps or vagrants, and it is to be hoped that a serious effort will shortly be made to deal with the problem presented by the existence of this class. It is not only on philanthropic grounds that steps in this direction are urgently called for; the mere instinct of selfishness or prudence dictates to the well-to-do portion of the community the necessity for abating the evil, when it is considered how often outbreaks of epidemic disease have been traced to infection carried by tramps, and how great and preventable a sacrifice of lives and money is thus incurred. But as in the case of physical disease, so here it is impossible to devise adequate remedies for the condition in question until we possess exact knowledge of the pathology—the causation and real nature—of the social defect. Until we obtain such knowledge it must be impossible to apply other than empirical measures of relief. Symptoms have been combated, outward manifestations suppressed, but the root of the evil has remained unaffected. Severe measures may have succeeded, in particular localities, in diminishing the number of admissions to the tramp wards of the poorhouses, but the total number of vagrants throughout the country has continued to increase, and will, we fear, increase until some great and organised measures of relief can be devised.

The study of the problem of vagrancy has been defective owing to the difficulty presented by attempts at investigation. The class of tramps is an unsavoury object of research and its members are generally suspicious of inquirers and unwilling to discuss their circumstances and the causes of their submergence. From time to time some enthusiastic inquirer has descended into the abyss and passed as a tramp for the nonce—some journalist in search of copy, *audax omnia perpeti*, or some amateur philanthropist; but owing perhaps to lack of training in social problems the fruit of their investigations has been so far small. A serious attempt to grapple with the question by personal research among the outcasts themselves has recently been made by one well-qualified to turn the knowledge gained to good use and able to formulate suggestions for reform in our mode of dealing with the class of wanderers. In a volume entitled "Glimpses into the Abyss"[1] Miss MARY HIGGS relates her experiences as a denizen of many casual wards and humble lodging-houses and offers some practical advice as to the cause of the tramp evil and the best mode of dealing with it. Miss HIGGS's book is tragic enough, but there is no piling up of horrors to make a lurid story more revolting or more pathetic. It is obviously a record of first-hand and searching scrutiny, by one who is quick to see, well equipped to observe, and fearless in putting her impressions to the test. A study of her work cannot fail to correct some of the errors into which the uninitiated person usually falls, for she throws a new and instructive light upon the question of the attitude to be adopted towards the roving population which forms the lowest stratum of our civilised state. It is too often assumed that all "tramps," the dilapidated specimens of humanity met with on the high roads walking wearily from town to town, are Ishmaels who have taken to the vagabond's life owing to laziness of disposition, who exist by begging and terrorising the cottagers along their route, and who are enabled to live in unmerited comfort owing to the mistaken leniency of our system of Poor-law administration. That there are a considerable number of individuals who would fairly answer to such a description is unfortunately true enough but Miss HIGGS supplies evidence that goes far to prove that these persons form a comparatively small proportion of the vagrant population. Most of those who claim the shelter of the casual ward are of distinctly higher type. They consist of workers who are unemployed but who are honestly willing to work if they can find suitable occupation. When this truth is once pointed out it is not difficult to see that there must be a large number of such unfortunates wandering in search of work. One of the assumptions of the political economist is that capital and labour are both mobile and readily able to migrate from one industry to another. How false this assumption is in the case of the individual labourer is gradually being discovered. A skilled workman thrown out of work is a wasted asset of national wealth. Even the unskilled has to transfer himself painfully to some other locality to find work, and to do so he must tramp on foot if he has not money enough to pay a railway fare. Just now the number of unemployed is large, for many industries are declining and few new ones seem to arise to take their place; hence the number of men who are out of work and obliged to wander in search of employment is also large. What is the prospect for such a vagrant, an honest man at the outset of his migration? He must repair to the tramp ward to be herded with the dirty and the vicious. Miss HIGGS shows that the hospitality which he will receive at the hands of certain authorities is not calculated to leave him a particle of self-respect or much chance of remaining the average good citizen that he may hitherto have been. He may be given food far worse than that supplied to criminals in prison and insufficient to keep up that modicum of strength with which he set out to look for work, and on this food be expected to perform a task of labour harder than that of a convicted felon. The alternative is the common lodging-house and Miss HIGGS shows that in these places such a vagrant may be lodged in insanitary quarters, left unprovided with the essentials of common decency, and compelled to sleep in a garment which has already been worn by an unknown number of dirty predecessors in misery, amid verminous companions, on a bed seemingly contrived as an instrument of torture. Little wonder, where such things occur, if a few weeks of the life make of a respectable workman a despondent outcast or a criminal. For the woman who has fallen on evil days it is even worse. She is irresistibly driven to a life of prostitution when the pressure of poverty is aided by the constant association with abandoned characters. We know that medical men have done all in their power to remedy maladministration of the law, and over and over again it has been pointed out that a badly kept tramp ward is a focus of danger to the community; but the abuses remain, and the assistance of Government will be required to deal with them systematically.

---

[1] Glimpses into the Abyss. By Mary Higgs. London: P. S. King and Son. 1906. Pp. 331. Price [illegible] net.

Upon Miss HIGGS'S excellent observations certain indications follow for improving the state of things now prevailing in parts of the United Kingdom. First of all it is necessary to discriminate between the hopeless loafer who will not work, the true worker in search of a job, and the man who is physically unable to earn a living by manual toil. This may not seem easy of accomplishment but it is not so difficult as appears. The last class can be detected only by careful medical inspection, but being so identified can be more or less eliminated. Then if a reasonable task were set to all applicants for relief the able worker would willingly perform it and should thus earn for himself a substantial meal and clean sleeping accommodation. The idler who refused or scamped the work should be treated as the social danger which he actually is and sent to prison or to some labour colony of a penal type. Miss HIGGS would have the seeker after employment helped on his way by the provision of a ticket entitling him to food and lodging in return for a task of work at the next station on his road, while by some system of public labour bureaux information as to hands needed in particular industries in different parts of the country should be made available to all. Here Miss HIGGS is in line with every practical thinker; the suggestion has been plentifully made and has been supported in our columns before now. Much might also be done for those who are not absolutely indigent by provision of cheap yet sanitary lodging-houses in which they could find accommodation while looking for work, thereby avoiding the common lodging-house as it now exists. Common lodging-houses require far more exacting scrutiny than they receive, and to this end we would urge upon the Government the absolute necessity of giving some security of tenure to medical officers of health. Common lodging-houses are frequently valuable private property, from which category we omit those managed—and for the most part admirably managed—by the Salvation Army, and in the present state of the law it may be impossible for a medical officer of health to obtain an abatement of abuses which stare him in the face. The tramp wards of our workhouses, despite Miss HIGGS'S unfortunate experiences, are not the source of public danger that the institutions controlled by private persons for private profits are known to be. The medical officer of health, for every conceivable reason of public policy, ought to be set in a strong position to deal with these places.

◆

The Registration of Opticians.

REFERENCE has frequently been made in our columns to the ambitious schemes of opticians, as well as to a Bill before Parliament for the purpose of registering opticians and thus supplying them with an official and professional status. This apparently harmless procedure really means the licensing of working opticians, druggists, and others who have received no medical education, to prescribe spectacles. The opposition to the Bill by the medical profession is being put forward by a joint committee of the Ophthalmological Society and the British Medical Association, and we may be sure that in their hands the logical arguments against such an anomaly will obtain proper prominence. The matter is one which affects the majority of general practitioners and not only the ophthalmologist, for the principle at stake is no less than the infringement of the rights and the prerogatives of the medical man. The public are as yet ignorant in matters of this nature. Too readily they fly off to the prescribing druggist for an aperient pill or a headache powder, or to the optician for spectacles, and their ignorance prompts them to see in the protests of medical men only a selfish resentment. We do not say that medical men are more altruistic as a class than other citizens —whatever we may think, but it is certain that unqualified medical practice of all sorts is perilous to the public weal. We return to the subject of the registration of opticians with the hope that the continual discussion of the matter will make the true position more evident to the public.

In the *Ophthalmic Review* for September of this year Dr. A. FREELAND FERGUS states the case for the medical man in much the same terms as it has been frequently stated before by our medical contemporaries and ourselves. He rightly observes that "no one is competent for ophthalmic work who has not had a very extensive training in the profession of medicine generally." He points out that registration might prevent the totally unqualified optician from prescribing glasses but questions "very much if any such legislation will be put on the statute book." We consider that it is about as probable as preventing druggists from prescribing. But Dr. FERGUS regrets that there is no British diploma or degree giving to its holder a qualification in ophthalmic medicine and surgery, and here we are not prepared to follow him. He would have a special register for ophthalmologists like that for dentists, separate from the general Medical Register. He advocates a very extensive curriculum for the ophthalmologist. The ophthalmic student should, in his opinion, have a thorough knowledge of plane trigonometry and some idea of the

pumping-station and the chalk formation underlying may at any time supply a mixture which will speedily be distributed to hundreds of thousands of water consumers with results too deadly to contemplate." Mr. Sandeman then refers to "myriads of flies and thousands of rats," which this refuse has been instrumental in attracting and to the risk which is thereby incurred of the distribution of fly- and rat-borne disease into houses. Although perhaps Mr. Sandeman is allowing himself a little latitude in certain directions, more especially, perhaps, in speaking of *midden* refuse—if he uses this term as implying the presence of human excreta—we can fully sympathise with him. The refuse in question is, we expect, ashbin refuse, which as a rule contains, in addition to ashes, much vegetable and some animal waste, a combination which is always liable to produce a peculiar condition of sore-throat and may at times give rise, by wind- or fly-borne infection, to diarrhœa or diphtheria, or conceivably, through infected rags and such-like, to enteric fever, an aspect of the question which is rendered more serious in this instance by the circumstance that the refuse is alleged to be in the vicinity of a chalk well supplying a very large population with drinking-water. Risk in this sense depends, however, upon the extent to which the chalk formation is fissured and uncovered by any impermeable formation. The remedy may be difficult, especially if the refuse is used for any industry such as brick-making, in which case action under Section 91 of the Public Health Act, 1875, might fail on the pretext "that the accumulation or deposit has not been kept longer than is necessary for the purposes of the business or manufacture and that the best available means have been taken for preventing injury thereby to the public health." If, for instance, the refuse were carefully covered over with earth so as to prevent disturbance by wind or carriage of filth by flies it might be held that the best available means had been taken. But if this were the case in the present instance it is unlikely that the nuisance would be detectible "for over a radius of a mile." The question as to whether the nuisance is one which might be dealt with by means of by-laws under Section 44 of the Public Health Act, 1875, would depend upon the precise position and source of the accumulation here in question. But we would advise Mr. Sandeman to procure a copy of a report on manure nuisances[1] which was made to the Local Government Board by Dr. H. Franklin Parsons as this may, we think, help him to devise a means of attacking the nuisance of which he complains. It is, of course, much easier to deal with nuisances of this nature in an "urban" than in a "rural" district, and we fear that in this case a "rural" area may be in question. But in many "rural" areas the conditions are in places practically "urban," and if this be so in this instance it may be easier to remedy matters.

THE FRENCH SURGICAL CONGRESS.

The Nineteenth Congress of the French Association of Surgery will be held at Paris from Oct. 1st to 6th. The President is M. Monprofit of Angers, professor at the Angers School of Medicine and surgeon to the Hôtel Dieu of the same town. The Vice-President is M. Berger, professor at the Faculty of Medicine and surgeon to the Necker Hospital. The general secretary is M. Charles Walther, Professor Agrégé at the Faculty of Medicine and surgeon to the Pitié Hospital. The three special subjects for discussion are: (1) surgery of the large venous trunks; (2) ways and means of access to the thoracic cavity from the point of view of operation; and (3) ectopy of the testicle and its complications. During the congress an exhibition of surgical instruments and of surgical dressings and the like will be on show, and show-cases will be provided for members of the congress for the purpose of exhibiting instruments or apparatus. The list of members of the congress includes a number of foreign surgeons as well as most of the French surgeons, and we are sorry to see that among the foreign surgeons those from our own country are in a decided minority. We regret this all the more inasmuch as those of our countrymen who have visited the congress always return with nothing but praise for it. The scientific side of the meeting is not interfered with by excess of hospitality, but such hospitality as there is is carried out with a grace, kindness, and thoroughness which our neighbours across the Channel know so well how to show. Possibly the date of the meeting being the first week in October makes it somewhat difficult for British surgeons to attend, but we hope in future that the names of British surgeons will be conspicuous in the list of members by something else than their absence.

SHOWER BATHS IN SCHOOLS.

At a meeting of the Medical Officers of Schools Association held on June 14th Mr. Frederick Rose, a gentleman connected with the education department of the London County Council, read a paper on the Use of Shower Baths in Schools in England and on the Continent. In this paper, which has now appeared in pamphlet form,[1] Mr. Rose says that warm shower baths with soap, followed by a moderately cold douche, form the ideal system for cleansing and stimulating the bodies of school children. The cleansing process is more thorough than in any other practical system, the dirty water is instantly carried off, fresh water is constantly supplied, the danger of infection is obviated, and the physiological action of the water is rendered most effective. Slipper baths are out of the question for large numbers of children, being too slow, costly, and capable of conveying infection; the invigorating effect is, moreover, entirely wanting, as the bathing takes places in stagnant water at a constant temperature. Mr. Rose considers that all children in elementary schools should have at least one shower bath per week. The propagation of infectious diseases in schools would thereby be decreased and the habit of cleanliness once acquired would remain with most of the children throughout their lives. Shower baths have been adopted for schools in Germany, Austria, France, Switzerland, Belgium, Holland, Norway, and Sweden, but in the elementary schools of Great Britain and Ireland the only shower baths provided are four douches at the "Pulteney" School, Shaftesbury-avenue, London, presented to the school some years ago by the Hon. Dudley Campbell. In Bradford the swimming baths are supplied with a small number of douches and all persons are required to use them before entering the swimming pool but no system of shower baths has been introduced. Swimming instruction is given to school children in Edinburgh, Glasgow, and a few English provincial towns besides Bradford but shower baths are not provided. In Germany the circumstances are quite different. To quote only three cities, out of 283 elementary schools in Berlin 62 are provided with shower bath installations; of the 30 elementary schools in Frankfort-on-the-Main 26 have shower baths; and in Munich 35 out of 53 elementary schools have shower baths. In the German schools the shower baths are completely free and no compulsion is used. The bathing takes place during school hours, but generally not during the last hour, so as to diminish the possibility of chills being contracted. In some towns the children bathe with bathing garments, but in other towns without them. In some towns they bathe entirely in common; in other towns a certain number of undressing and douching boxes are provided for the older children; and in a few towns, notably Cologne, separate undressing and douching boxes are provided for all children without exception. The average duration of a bath seems to be from 20 to 30 minutes; the showers are generally started at about blood heat and gradually reduced to a temperature varying from 55° to 70° F. As a rule the children stand in a large shallow trough during the douching operation and the douching itself is carried on either by means of single sprays to each child or by sprays which cast the water further apart and form a kind of rain. In the newer German public swimming baths no persons are allowed to enter the swimming pool without having previously soaped and washed themselves under the douches provided for this purpose. Mr. Rose states that the half hour devoted to shower baths per week has amply repaid itself in the improvement of the clothing and health of the children; it seems probable that it has also produced an increased capacity for learning, as well as some diminution of verminous conditions, skin diseases, and infection. In conclusion, he makes a variety of suggestions and estimates with respect to the construction and the use of school shower baths.

---

[1] Extracts from the Annual Report of the Medical Officer of the Local Government Board for 1891-92. On Manure Nuisances, by H. F. Parsons, M.D. Eyre and Spottiswoode.

[1] London:

THE PREVENTION OF SMOKE IN LONDON AND IN PROVINCIAL TOWNS.

Is there any reason why certain provincial towns should apparently be exempt from that clause of the Public Health Act which provides that "any fireplace or furnace which does not as far as practicable consume the smoke arising from the combustible used in such fireplace or furnace and is used for working engines by steam or in any mill, factory, dyehouse, brewery, bakehouse, or gaswork, or in any manufacturing or trade process whatsoever" shall be deemed to be a nuisance liable to be dealt with summarily and a penalty imposed? Commendable work in the direction of abating the smoke nuisance in and around the metropolis has during recent years been done owing to the vigilance of our health authorities, who have been stirred to exercise their duty in this matter by the revelations published in THE LANCET and by the action also of the Coal Smoke Abatement Association under the presidency of Sir William Richmond. The condition of the London atmosphere has undoubtedly improved during recent years owing to a decided abatement of the smoke nuisance, and we utterly fail to understand why a similar improvement is not attempted in provincial towns and especially in those which are the centre of busy manufacturing areas. We may refer to Nottingham as a brilliant exception, for there, we believe, the lace manufacturers were compelled to abate the smoke nuisance purely in their own interest, for the smoke spoiled their goods. The shortening of lives by a compulsory existence in air intensely and constantly polluted with smoke is a much more serious matter than the spoiling of lace. The example of Nottingham is a splendid object lesson and proves absolutely that the smoke nuisance from factories need not be. Yet we still have "the black country" with us as smoke-besmirched as ever. The condition of the air between, say, Wolverhampton, to give one example, and Birmingham is a disgrace to any civilised community. Smoke of the filthiest description hangs as a dark pall for miles, absolutely shutting out the sun and the sky. Thousands of chimneys pour forth torrents of black smoke. "Torrents" is no exaggeration, while to say in the words of the Act that these chimneys send forth "black smoke in such quantity as to be a nuisance" conveys but the feeblest impression of the real state of affairs. Under this pall at intervening places like Dudley, Oldbury, West Bromwich, and elsewhere, thousands of work-people, men, women, and children, take their recreation, and it is pitiable to witness under what intensely impure conditions of the air these people attempt to preserve a healthy body. The pollution of the air is as much a scandal as the pollution of water and food, and the interference of the State is badly and instantly wanted in order that this wanton and wholesale defilement may be stopped. It would be idle to deny that this evil is a serious factor in the high rate of mortality which smoke-drenched districts commonly show.

FOREST FIRES IN SOUTHERN EUROPE.

WITHIN the zone bounded on the north by Grenoble and Toulon and on the south by Algiers, on the west by Logrono in Spain and on the east by Catanzaro in Italy, there have been, coincidently with the recent heat wave, a series of forest fires disastrous to all these countries, but more especially to Italy and Spain, where the problem of replanting the denuded hillsides is of clamant urgency. Reckless tree-felling in both peninsulas for carpentry in all its branches and not least for fuel has reduced immense tracts of territory to prairie or to what the Italians call "macchia"—that is, stunted forest growth, useful neither for timber nor for fuel, and rendering tillage or even pasture difficult and precarious. This fatal practice has been going on for centuries—changing the climate for the worse, rendering the rainfall uncertain, between autumnal inundations and summer droughts, circumscribing agriculture, and spoiling the amenity of the landscape. Spain was an early sinner and suffered in this respect, her timber becoming prematurely exhausted, so as even to restrict her ship-building and gradually to diminish, if not to extinguish, her mercantile marine. Italy has sinned and suffered still more—for this among other reasons that, having become for half a century the winter resort of the northern races with their craving for heating and fuel, she is exposed to a drain on her forest-growth from which other countries are exempt. The *Vox Urbis*, an able Latin journal published in Rome, devotes in its current number a leading article to the subject—"De Silvis Lege Tuendis"—and points out to Italy how sorely she needs "to take a leaf," literally so, out of the trans-Alpine book. While on her own side of the water-shed her rivers are gravel pits for ten months of the year, thanks to the excessive floods of the other two—in low water, so to say, after a "run on their own banks"—the corresponding streams on the Swiss side maintain a steady, equable flow, in summer as well as in winter, and this because of the wise law, stringently enforced throughout the Confederation, that no tree shall be felled without its replacement by the planting of another. By this means the conservation of moisture, its gradual, almost imperceptible, evaporation, and its no less gradual descent in showers, keep the rivers regularly supplied all the year round, not only preventing floods but turning the said rivers into agents for the development of electric energy and making their banks the seat of prosperous and multiplying factories of the steel and iron and other industries. Poor Italy, on the contrary, having no such law and, late in the day, beginning vigorously to enact, if feebly to enforce, an imitation of it, has the mortification of seeing her water-supply alternating between short-lived inundation and prolonged drought with all their disastrous consequences and, unkindest cut of all, the electric agency which, through Galvani and Volta, Nobili and Matteucci, she made known to the world, utilised by a rival power on the northern side of the watershed—taken out of her hands indeed—as an industrial and lucrative force, sorely as she needs new outlets for enterprise and sources of gain. Late in the day, we have said, has she awakened to her suicidal treatment of her woods and forests and now realises that, thanks to the floods that, in the autumn especially, devastate her hillsides and plains, the binding soil required for replanting those hillsides is washed away and the task of reafforesting becomes next to impossible. Within living memory the Sabine range so conspicuous from Rome and so dear to the scholar for its associations with the Lucretilis and Ustica of Horace was waving with foliage, a welcome retreat in the dog-days, when—

> "...... Pastor umbras cum grege languido
> Rivumque fessus quaerit et horridi
> Dumeta Silvani, caretque
> Ripa vagis taciturna ventis."

Now, owing to the increased demand for fuel in the ever-multiplying hotels and *pensions*, that mountain slope is bare limestone, reduced to bed rock on which planting is impracticable. When reafforesting has thus become Italy's "prima cura," when every tree is precious and likely to become more so from the difficulty of replanting, we can understand the bitterness with which Italians read of woods on fire ("boschi in fiamme") in Liguria, in Calabria, even under the shadow of the Vatican itself, where many roods of plantation on the lower spurs of the Janiculars were the other day reduced to charcoal. Dr. Angelo Celli, professor of public hygiene in the Roman School, is, we are happy to see, "keeping at" the Government for the conservation of existing woods, the replenishment of those so sadly thinned, and the resuscitation of such as are no more. From his seat in Parliament he has extorted promise after promise from the Ministers of Agriculture and of Public Works that the legislation in this sense, so thorough in theory, should become as thoroughly efficacious in practice. Our sympathies are quite with him. Pity it were that the agitation for new ironclads and "destroyers" should override the young movement for reafforesting, that the clamour for quick-firing guns and field batteries of a novel type should drown the appeal of Hygieia, echoed by the wail of the Hamadryad.

PRESERVATIVES IN MILK.

THE Local Government Board for Scotland has issued to the clerks of local authorities a letter directing their attention to the subject of the addition of preservatives to milk. This matter was carefully considered by a departmental committee of the Local Government Board for England. In its report the committee stated that preservatives were objectionable on the ground of public health and were also unnecessary for the purposes of the milk trade. The Local Government Board for Scotland accordingly suggests that the local authority should cause samples of milk to be taken with a view to ascertain the presence of substances commonly in use as preservatives—e.g., formalin and boron substances. When such samples are forwarded to the analyst he should be informed of the purpose for which they have been taken. It is suggested that the local authority should first warn milk traders that action will be taken under the Sale of Food and Drugs Acts in instances where preservatives are reported in milk, and should thereafter, when the presence of any added preservative is reported in a sample of milk, regard the case as one for the institution of proceedings under these Acts. In some districts in England, action under Section 6 of the Sale of Food and Drugs Act, 1875, has been frequently and successfully taken in such cases, it being held that, when a purchaser asks for milk and is supplied with milk *plus* a preservative, he does not receive an article of the nature, substance, and quality demanded, and is prejudiced thereby. Vendors of milk may attempt to evade a prosecution by making a declaration that the milk contains some added preservative and the Board suggests the desirability of sampling in such cases. The nature of the declaration made should in all cases be carefully recorded by the officer taking the sample and should also be reported to the analyst when the sample is transmitted for analysis. Where preservatives are reported in milk thus sold the question will arise whether, in view of the nature and quantity of the preservatives added, it can be considered that the article has been rendered injurious to health, or that the purchaser has been prejudiced to an extent which would justify the institution of proceedings under Section 3 or Section 6 of the Sale of Food and Drugs Act, 1875, notwithstanding the declaration made at the time of the purchase. In this connexion the Board is advised that, as regards formalin and boron preservatives, the presence in milk of formalin to an amount that is ascertained by examination *within three days of collecting the sample* to exceed 1 part in 40,000 (1 part of formic aldehyde in 100,000) raises a strong presumption that the article has been rendered injurious to health and that the purchaser has been prejudiced in the above sense. Similar presumption is raised where boron preservatives are present in milk to an amount exceeding 57 parts of boric acid per 100,000, or 40 grains of boric acid per gallon. It is also suggested that the addition of preservatives to skimmed milk, separated milk, and condensed milk should be watched and controlled on similar lines. A similar letter was issued by the Local Government Board for England in July last and was referred to in an annotation in THE LANCET of July 21st, p. 178.

PHLEGMONOUS ENTERITIS.

PHLEGMONOUS gastritis is a very rare disease but phlegmonous enteritis is still rarer; only seven cases appear to have been recorded. In the *Johns Hopkins Hospital Bulletin* for August Professor W. G. MacCallum has reviewed the literature of the subject and reported the following case. A negro, aged 75 years, was taken to hospital complaining of pain in the abdomen and vomiting. Three weeks before he was struck by a car in the street and taken to hospital with a scalp wound. For a week he remained in hospital and complained of considerable abdominal pain. He returned home and appeared to be quite well until the day before his second admission, when he awoke with pain in the abdomen. On admission he indicated the site of pain as the right lower ribs, the epigastrium, and the left flank. Every few minutes he regurgitated without effort yellowish bile-stained fluid of a foul, faintly fæcal odour. He looked ill, the tongue was moist, and the lips were dry. The abdomen was full but not distended and there was bulging in the flanks. On deep palpation there was general tenderness which appeared to be slightly greater below the umbilicus. There was relative dulness in the left flank. Peristalsis was visible over the abdomen. The temperature was 100° F., the leucocytes were 24,000, and the urine contained albumin and numerous granular casts. Because of the signs of obstruction laparotomy was performed. On the left side of the abdomen was a slight excess of turbid fluid. The beginning of the jejunum was markedly thickened, had a brawny appearance, and was a little darker than the surrounding bowel. On palpation much enlarged rugæ could be felt. The serous covering was slightly injected, had lost some of its gloss, and showed a few fine flakes of fibrin. Death occurred on the following morning. At the necropsy the mucosa of the stomach was found everywhere thickened, studded with mushroom-like polypoid masses, and covered with thick mucus, and it showed abundant ecchymoses. Just below the pyloric ring were one or two small, irregular, punched out ulcers. The intestine was greatly enlarged from a point about five centimetres below the pylorus for a distance of 30 or 35 centimetres. Its walls were much thickened so that it stood out as a stout rigid tube which abruptly was continuous with normal collapsed intestine. The lumen of the affected intestine was filled with a soft, yellowish-white, pasty, granular material. The mucosa was very pale and greyish white and showed a few minute hæmorrhages.

malaria occurred in the room. The dates suggest that he was the source of infection of the other soldier. But the men did not appear to have any particular communication with each other. Major Copeland and Major Smith suggest that the disease was conveyed by a flea or a bug. They also think that the case helps to explain the cause of some failures to stamp out malaria by destroying mosquitoes. This case would not have been diagnosed if the malarial parasite had not been found in the blood. It is therefore quite possible that other cases in which malaria was contracted in this country after it ceased to be indigenous may have been overlooked, as it is only in recent years that examination of the blood for the parasite has become general. Previously the fact that a patient had never been out of England would, as in the case now reported, have been thought sufficient to exclude malaria.

PATENT MEDICINE TRAFFIC.

THE figures which were recently published in THE LANCET showing the amount of duty paid on patent medicines in one year afford convincing proof of the magnitude of the business. It is instructive to calculate the face value of the medicines as represented by the value of stamps sold. The figures are as follows:—

Number of packages.	Full value per package.	Total face value.
31,322,832	1s. 1½d	£1,761,909
7,232,432	2s. 9d.	631,963
1,154,092	4s. 6d.	259,670
134,357	11s.	73,896
14,808	22s.	16,288
12,625	33s.	20,831
Total ... 39 851,146	—	Total ... £2,764,557

The sale of patent medicines for the year under consideration averaged, therefore, more than one package for each inhabitant of this country, with a face value of over £2,750,000 sterling. *This nefarious traffic will go on increasing so long as the majority of newspaper proprietors are untrammelled by legal restrictions and unfettered by principles. It is the unscrupulous newspaper proprietor who* acts as the middleman, enabling the quack by misrepresentation and often by unmitigated fraud to take advantage of the ignorance and prejudice of the public.

ROTTEN EGGS AND THEIR USES.

AT the Thames police court on Sept. 19th summonses were heard against three separate defendants, bearing names suggestive of their Russian origin, all of whom were found guilty of similar offences and were fined respectively £8, £12, and £3, with costs in addition. They were bakers and the information against them was stated to have been given by rival traders. These were certainly justified in supplying it, for the three defendants in order to glaze their bread were in the habit of buying eggs which were the cheapest that they could obtain and unfit for human food. One of them was found to have upon his premises no less than three and a half gallons of liquid filth standing ready for use, and as this must be a large amount to be consumed in the manner indicated in one day it seems probable that some of it was destined to be kept for future occasions. It is a matter of frequent observation that people, educated and uneducated, associate a certain appearance in their food with good quality, and stipulate for the former while unable to detect the absence of the latter. Much of the adulteration of milk and of bread is due to an idea that milk ought to have a yellow tinge and that the whiter bread is the better it is also. The glazing on some pastry and on many kinds of fancy bread affords no evidence of richness or of any skill on the part of the maker but apparently, like the sugary glazing on some varieties of buns, it attracts. There is a conventional idea that the surface of rolls or pastry or buns should look brown and shiny and eggs in the case of an unsweetened article supply the varnish required. This may be perfectly harmless, but there are always bad eggs in the market to be bought at a very low rate compared with fresh ones, and the temptation to the needy and unscrupulous is obvious. It seems a pity that housekeepers should stipulate for appearances which in no circumstances can be of any value but which may lead to their buying food containing nasty and unwholesome ingredients.

DISINFECTION BY FORMALDEHYDE.

A VALUABLE contribution to the subject of disinfection by formaldehyde forms the substance of a paper by Mr. Daniel Base, of the Division of Pharmacology, Hygienic Laboratory, United States Public Health and Marine Hospital Service, which is published in the *Journal of the American Chemical Society* for August. The investigation was undertaken in order to determine the amount of formaldehyde gas given off into a room, specially designed for the purpose, from a definite volume of formalin by five well-known methods and to fix the relative values of these methods as to the yield of formaldehyde gas. The methods compared were: 1. The permanganate-formalin method, by which formalin is poured upon crystals of potassium permanganate; the reaction is completed in about five minutes. 2. The autoclave method whereby an autoclave is first charged with a definite mixture of formalin, glycerine, calcium chloride and water; the pressure is then raised to between 50 and 60 pounds, the cock is opened, and the ejection continued until the pressure falls to about 20 pounds; the pressure is then again raised and the process repeated so long as vapour continues to escape from the nozzle of the autoclave. 3. The sheet-spraying method, which simply consists in hanging up in a room two large sheets at an angle of about 45°, damping them and spraying them uniformly with a given quantity of formalin. 4. The Kühn lamp method, based on the generation of formaldehyde by the partial oxidation of methyl alcohol. 5. The Trenner-Lee retort method, by which formalin is simply heated to the boiling point in a retort in such a manner that the issuing formaldehyde gas and water vapour are passed into the room. The results obtained must be interpreted as representing the quantities of formaldehyde gas that may be expected to be present in a fairly air-tight room on a fairly still day, and after a certain interval of time which varies with the method used. According to the volume of formaldehyde yielded Mr. Base arranges the methods in the following order: (1) the Trenner-Lee retort method which gives the best yield; (2) the autoclave method; (3) the permanganate-formalin method in the proportion of 300 grammes of the salt to 600 cubic centimetres of formalin; (4) the sheet-spraying method; (5) a modification of (3), consisting in the addition of 300 cubic centimetres of water to 375 grammes of potassium permanganate and 600 cubic centimetres of formalin; and (6) the Kühn lamp method. For simplicity and expedition Mr. Base regards the permanganate-formalin method as preferable to all the others. The yield of formaldehyde gas can easily be increased by using larger quantities of materials. Although the sheet-spraying method does not give at any time so high a percentage of the gas it has the advantage that a uniform amount of gas is kept up for a long time. On the other hand, the modified

constantly diminis

six hours is less

method. By the autoclave method there is a loss of formaldehyde in the autoclave by polymerisation or decomposition. The Trenner-Lee retort method, although yielding appreciably more gas than the autoclave, requires more than twice the time to exhaust the apparatus. With the Kühn lamp the yield of formaldehyde is low; but this method possesses the merit of producing more moisture in the air of the room than the other methods described. This point is of importance, since it has been stated by H. von Brunn[1] and others that it is preferable nearly to saturate the air of the room with moisture in order to favour the condensation of formaldehyde on the various objects in the room. Mr. Base suggests that a greater degree of humidity in the air can readily be obtained with the permanganate-formalin method by using an ordinary tin or copper still. Finally Mr. Base quotes the conclusions of a recent experimenter[2] as to the practical requirements for an effective formaldehyde disinfection: (1) five grammes of formaldehyde (absolute) should be present in each cubic metre of space (0·1416 gramme per cubic foot), and should be allowed to act for seven hours; (2) the temperature of the room should not fall below 50° F., the best temperature being from 68° to 77° F.; and (3) the strength of the formalin should be ascertained.

"SAVOURY DUCK."

At the recent conference of sanitary inspectors at Blackpool Mr. James McPhail, M.R.C.V.S., chief food inspector at Hull, read a paper in which he dwelt at length upon facts which had come under his notice bearing upon the desirability of universal public slaughter-houses. The point which he emphasised was that in the interest of the public health it is necessary not merely that there should be inspection but that every carcass slaughtered should be examined at a stage when the examination can be made complete and effective. When a number of private slaughter-houses are used daily this is impossible without a very large staff of inspectors, and when the inspection is not made immediately the most important part, the offal, can be removed from the carcass and dissociated from it, diseased portions can be excised, and articles of food destined to be bought by the humbler and less exacting members of the community can be placed upon the market, although in an unwholesome condition. The *Manchester Courier* thus summarises Mr. McPhail's account of the tricks of the butcher who caters for the poor:—"If a liver had an abscess in it the general way was to cut it out and use the remainder. Immature tape-worm cysts were called blebs. These were burst, but the heads, which developed into tape-worms, were allowed to remain. Livers loaded with hundreds of parasites, called flukes, were used, and sheep's lungs were the principal component part of that delicacy 'faggot,' or 'savoury duck,' or 'Yorkshire duck,' and those lungs, without exception, contain thousands of microscopic worms and their eggs. The working man who had not too much money to spend in his eating-house ordered his 'duck and potatoes.'" Allowing for deviations from the actual phraseology used by the speaker as may be due to the exigencies of an abbreviated report in a lay newspaper, we have here a forcible picture of the conditions under which the public are permitted, or rather are compelled, to purchase their food in spite of the maintenance of an expensive system of food inspection. The results, however, of their consumption of such articles of diet as those indicated are neither so immediate nor so readily traced to their source as to cause any urgent demand for reform on the part of those most affected. There are also the vested interests of the owners of the existing slaughter-houses to be considered whenever the reform takes place. Whatever may be the arguments for or against what is known as "municipal trading" we would suggest that it is at least as desirable in the public interest that, so far as it is possible, local authorities should own all the slaughter-houses as that they should embark upon schemes for tramways and electric lighting.

ANCIENT INDIAN MEDICINE.

Dr. Rudolf Hoernle has published in the *Journal of the Royal Asiatic Society* some Studies in Ancient Indian Medicine, treating of all the known commentaries upon Susruta's great text-book on general medicine entitled "Ayurveda Samhita." At present only one of the commentaries on it—that by Dallana, written about the eleventh century—is complete. Dr. Hoernle quotes previous writers who are concerned with Dallana's work. Susruta's text-book was printed in 1889, and Dallana's treatise upon it in 1891, at Calcutta. The latter gives the names of fifteen of the books upon Ayurveda Samhita which he had consulted but Dr. Hoernle traces extracts from other authors of whose works copies still exist and incidentally throws great light upon the history of Indian medicine. One of the earliest of these writers of any importance he shows to have been Jaljata, who wrote perhaps before the seventh century and of whose work we have no copy, but doubtless many extracts from it are to be found in the voluminous scholia contained in the later Indian medical writers treating of Susruta. Next in value to Jaljata was Gayadasa who commented upon the whole of Susruta's great book. Some of his work is preserved. One portion, relating to his views upon Susruta's work upon pathology and anatomy, is in a newly-found manuscript described by Professor Cordier and also in another at Cambridge. Dr. Hoernle has examined and now treats of this codex which numbers 68 leaves. It is interesting because it proves that Gayadasa had before him a different text of Susruta from the version that Dallana knew. Dr. Hoernle's essay treats of the dates of the various writers and will be invaluable to all students of Sanscrit medical literature.

Dr. Leonard P. Mark will deliver the presidential address before the West London Medico-Chirurgical Society at 8.30 on Friday, Oct. 5th. The subject will be Art and Medicine and the address will be illustrated by lantern slides of some pictures and works of art in British picture galleries and museums which are interesting from a medical point of view.

The Registrar of the General Medical Council is directed to state for information that Sir Victor Horsley has written to the President resigning his seat on the Council in order that the inconvenience of a separate election next year may be avoided.

A telegram from the Governor of the Mauritius, received at the Colonial Office on Sept. 21st, states that for the week ending Sept. 20th there were 18 cases of plague and 7 deaths from the disease.

The forty-seventh annual meeting of the New Sydenham Society will be held at 4.30 p.m. on Monday, Oct. 1st, at Mr. Jonathan Hutchinson's house, 15, Cavendish-square, London, W.

The opening address of the winter session will be delivered before the West London Post-graduate College on Wednesday, Oct. 10th, at 4.30 p.m., by Mr. C. B.

[1] Formaldehyddesinfektion durch Verdampfung verdünnten Formalins," Zeitschrift für Hygiene und Infectionskrankheiten, 33, 221 [illegible]

[2] G. Wegner: Zur Kritik der Formaldehyddesinfektion, Archiv für Hygiene, 39, 38 [illegible]

malaria occurred in the room. The dates suggest that he was the source of infection of the other soldier. But the men did not appear to have any particular communication with each other. Major Copeland and Major Smith suggest that the disease was conveyed by a flea or a bug. They also think that the case helps to explain the cause of some failures to stamp out malaria by destroying mosquitoes. This case would not have been diagnosed if the malarial parasite had not been found in the blood. It is therefore quite possible that other cases in which malaria was contracted in this country after it ceased to be indigenous may have been overlooked, as it is only in recent years that examination of the blood for the parasite has become general. Previously the fact that a patient had never been out of England would, as in the case now reported, have been thought sufficient to exclude malaria.

PATENT MEDICINE TRAFFIC.

The figures which were recently published in The Lancet showing the amount of duty paid on patent medicines in one year afford convincing proof of the magnitude of the business. It is instructive to calculate the face value of the medicines as represented by the value of stamps sold. The figures are as follows:—

Number of packages.	Full value per package.	Total face value.
31.322,832	1s. 1½d	£1,761,909
7,222,432	2s. 9d.	631,963
1,154,092	4s. 6d.	259,670
134,357	11s.	73,895
14,803	22s.	16,288
12,625	33s.	20,831
Total ... 39,851,146	—	Total ... £2,764,557

The sale of patent medicines for the year under consideration averaged, therefore, more than one package for each inhabitant of this country, with a face value of over £2,750,000 sterling. This nefarious traffic will go on increasing so long as the majority of newspaper proprietors are untrammelled by legal restrictions and unfettered by principles. It is the unscrupulous newspaper proprietor who acts as the middleman, enabling the quack by misrepresentation and often by unmitigated fraud to take advantage of the ignorance and prejudice of the public.

ROTTEN EGGS AND THEIR USES.

At the Thames police court on Sept. 19th summonses were heard against three separate defendants, bearing names suggestive of their Russian origin, all of whom were found guilty of similar offences and were fined respectively £8, £12, and £3, with costs in addition. They were bakers and the information against them was stated to have been given by rival traders. These were certainly justified in supplying it, for the three defendants in order to glaze their bread were in the habit of buying eggs which were the cheapest that they could obtain and unfit for human food. One of them was found to have upon his premises no less than three and a half gallons of liquid filth standing ready for use, and as this must be a large amount to be consumed in the manner indicated in one day it seems probable that some of it was destined to be kept for future occasions. It is a matter of frequent observation that people, educated and uneducated, associate a certain appearance in their food with good quality, and stipulate for the former while unable to detect the absence of the latter. Much of the adulteration of milk and of bread is due to an idea that milk ought to have a yellow tinge and that the whiter bread is the better it is also. The glazing on some pastry and on many kinds of fancy bread affords no evidence of richness or of any skill on the part of the maker but apparently, like the sugary glazing on some varieties of buns, it attracts. There is a conventional idea that the surface of rolls or pastry or buns should look brown and shiny and eggs in the case of an unsweetened article supply the varnish required. This may be perfect harmless, but there are always bad eggs in the market to b bought at a very low rate compared with fresh ones, and th temptation to the needy and unscrupulous is obvious. seems a pity that housekeepers should stipulate for appea ances which in no circumstances can be of any value b which may lead to their buying food containing nasty an unwholesome ingredients.

DISINFECTION BY FORMALDEHYDE.

A valuable contribution to the subject of disinfecti by formaldehyde forms the substance of a paper by M Daniel Base, of the Division of Pharmacology, Hygien Laboratory, United States Public Health and Marine Ho pital Service, which is published in the *Journal of t American Chemical Society* for August. The investig tion was undertaken in order to determine the amou of formaldehyde gas given off into a room, speciall designed for the purpose, from a definite volume formalin by five well-known methods and to fix th relative values of these methods as to the yield of forma dehyde gas. The methods compared were: 1. The perma ganate-formalin method, by which formalin is poured upo crystals of potassium permanganate; the reaction is com pleted in about five minutes. 2. The autoclave metho whereby an autoclave is first charged with a definite mixtu of formalin, glycerine, calcium chloride and water; th pressure is then raised to between 50 and 60 pounds, the coc is opened, and the ejection continued until the pressur falls to about 20 pounds; the pressure is then again raise and the process repeated so long as vapour continues t escape from the nozzle of the autoclave. 3. The sheet spraying method, which simply consists in hanging up in room two large sheets at an angle of about 45°, dampin them and spraying them uniformly with a given quantity o formalin. 4. The Kühn lamp method, based on the genera tion of formaldehyde by the partial oxidation of methy alcohol. 5. The Trenner-Lee retort method, by whic formalin is simply heated to the boiling point in a retort i such a manner that the issuing formaldehyde gas and wate vapour are passed into the room. The results obtained mus be interpreted as representing the quantities of formaldehyd gas that may be expected to be present in a fairly air-tigh room on a fairly still day, and after a certain interval o time which varies with the method used. According to the volume of formaldehyde yielded Mr. Base arranges the methods in the following order: (1) the Trenner-Lee retort method which gives the best yield; (2) the autoclave method; (3) the permanganate-formalin method in the proportion of 300 grammes of the salt to 600 cubic centimetres of formalin; (4) the sheet-spraying method; (5) a modification of (3), consisting in the addition of 300 cubic centimetres of water to 375 grammes of potassium permanganate and 600 cubic centimetres of formalin; and (6) the Kühn lamp method. For simplicity and expedition Mr. Base regards the permanganate-formalin method as preferable to all the others. The yield of formaldehyde gas can easily be increased by using larger quantities of materials. Although the sheet-spraying method does not give at any time so high a percentage of the gas it has the advantage that a uniform amount of gas is kept up for a long time. On the other hand, the modified permanganate-formalin method yields a constantly diminishing quantity of gas, which after five or six hours is less than is obtained by the sheet-spraying

Keetley, F.R.C.S. Eng., senior surgeon to the West London Hospital, at the hospital. Tea and coffee will be provided at 4 P.M. and after the address.

THE subject of the address of the incoming President (Mr. C. A. Ballance) before the Medical Society of London on Oct. 8th, at 8 P.M., will be "Then and Now in Surgery."

Mr. Obadiah Johnson, M.D. Edin., has been appointed an unofficial member of the Legislative Council of the Colony of Southern Nigeria.

Dr. James Macpherson Lawrie has been appointed Deputy-Lieutenant of the county of Dorset.

MEDICINE AND THE LAW.

Imprisonment for Debt.

PROBABLY a large number of Britons living in comfortable circumstances and not troubling themselves about the affairs of their humbler neighbours would tell an inquiring foreigner that imprisonment for debt was done away with long ago in these islands. They might, perhaps, add observations as to the physical and moral degradation which accompanied it, and illustrate them by reference to the fiction of Dickens, Thackeray, and other writers of the last century. As a matter of fact, however, or rather as a matter of law, a county court judge is given power to imprison debtors who do not obey his order to pay their creditors "when it is proved to the satisfaction of the court that the person making default either has or has had since the date of the order or judgment the means to pay the sum in respect of which he has made default, and has refused or neglected, or refuses or neglects, to pay the same." This has been the law since 1869. In 1875 4063 "judgment debtors" went to prison for various terms, in 1895 8190, and in 1905 11,405, and it must be remembered that these were consigned, not as debtors to a prison set apart for them, but to the ordinary gaol to which the pickpocket and the vagrant go. The increasing figures prove that a large number of persons are not afraid to incur debts which they will not be able to pay, and that the possibility of going to prison does not act as a deterrent to such as these. It is also notorious that the process of the court intended to be applied to those who wilfully disobey—those, in short, who can pay but will not—is abused; it becomes the means by which the "screw" is put upon persons who under its action can obtain money by borrowing it or by appealing to the sympathy of relatives better off than themselves. The system undoubtedly leads to lying and perjury in the county courts; it tends to demoralise those who go to prison and their families, whom they probably leave to go to the workhouse; it is costly to the public; and it benefits principally those persons who can use it as a method of terrorising their debtors. There are two sides to the question and the small trader requires protection from dishonest customers, but at the same time many contend with reason that the abolition of all imprisonment for debt, or its retention only for those cases where the debtor clearly and beyond question is defying the court, would have a beneficial effect on the community. It would cause cash payments to be insisted upon, or the exercise of self-denial on the part of the would-be purchaser, who in existing circumstances is tempted to increase his difficulties by purchasing upon credit. The committal to prison in a year of 11,000 persons who have committed no crime is a grave matter for medical men to contemplate, and a House of Commons in which the working man is largely represented should find time to give serious attention to the recently issued county court returns. Prison is prison whatever the reason may be which causes the detention; and in the long run many prisoners connotes many miserable homes, much privation, and much disease. The sequence is a fairly direct one.

THE GUILD OF ST. LUKE.—The customary annual service of the Guild of St. Luke will be held in St. Paul's Cathedral on Wednesday, Oct. 17th, at 7.30 P.M.

Public Health and Poor Law.

LOCAL GOVERNMENT BOARD.

ANNUAL REPORTS OF MEDICAL OFFICERS OF HEALTH.

City of Glasgow.—The population of this city, 809,936 is still the largest in the United Kingdom with the exception of that of London, and Dr. A. K. Chalmer makes good use of the material afforded him. Durin 1905 he endeavoured to investigate the food habits of 55 families (over 3000 persons) in whose households case of infectious disease had occurred and, as was to hav been anticipated, the results emphasised the enormou importance of educating the poorer classes as to the foo values of the commoner articles of diet. Dr. Chalmer thinks that the establishment of food canteens in the poore districts where substantial fare could be purchased at reasonable cost would prove of great and immediate benefi and he thinks that the abuse of such establishment could be prevented by visiting the children at thei homes. He points out that in the poorer parts o Glasgow there are many motherless families where th children's food is a succession of tea meals, with littl variation, and with no trustworthy help available. In hi inquiry he classified the diets into "good," "medium," and "bad," and it is interesting to observe the relations o the preponderating diet to the size of the dwelling. In the one-apartment dwellings the feeding was 27 per cent. good, 40 per cent. medium, and 33 per cent. bad, as against, in the two-apartment dwellings, 46 per cent. good, 44 per cent. medium, and 10 per cent. bad, while as regards the three-apartment dwellings the feeding was 71 per cent. good, 24 per cent. medium, and 5 per cent. bad. The canteen system is being at the present time largely patronised by the French and there is no doubt much to be said for it. But it is to be hoped that in addition the education authorities will see that the children in the schools are taught by a simple kindergarten system how to purchase the most nutritious meal for a given sum. In dealing with the statistics of Glasgow Dr. Chalmers points out that the estimation of the marriage-rate upon the population as a whole is likely to lead to very erroneous conclusions, and that the better method of stating the rate is in relation to the unmarried females and widows aged 15 years and upwards. When the rate is estimated on the whole population basis the decrease in Glasgow during the last 30 years was only 4 per cent., whereas a decrease of 16 per cent. is demonstrated by the other method. An instructive inquiry as regards pulmonary tuberculosis was undertaken in Glasgow during 1905 but we have no space to summarise it here. We may, however, quote some very sensible remarks made by Dr. Chalmers as regards the classification of cases. He says: "For administrative purposes some classification is necessary, but this must obviously have reference rather to the object in view than to the pathological condition present. It cannot be too frequently reiterated that the prevention of phthisis will only be accomplished by removal of the conditions which foster it. Phthisis prevails in our midst because of the low standard of housing we are still perforce compelled to accept. No provision of sanatoria for early cases, or of homes of rest for the very advanced, will in the least degree abate the necessity for keeping this steadfastly in view. Forms of individual relief are useful and valuable adjuncts. They may provide for the segregation of the actively infective or place the incipient case in the way of improvement, but the reduction of phthisis in the past has proceeded without organised help of either kind. With the modern views regarding the part played by sputum, and especially by droplet-infection, in spreading the disease, however, some supervision of the individual may reasonably be added; and the form which this supervision should take suggests the administrative classification necessary." There were during 1905 one death from anthrax and one from glanders, both in the human subject. In the case of anthrax the evidence pointed [illegible] unknown origin as the possible source of

to 153 ohms; the resistance of the urine (not coloured blue) segregated from the left diseased kidney amounted to 93·5 ohms, or more than double the average normal resistance. The resistance of the urine (coloured blue) segregated from the right healthy kidney was 62·9. The hæmo-renal salt index of the diseased kidney was $\frac{153}{93{\cdot}5} = 1{\cdot}6$. The hæmo-renal salt index of the healthy kidney was $\frac{153}{62{\cdot}9} = 2{\cdot}4$. No allowance has, however, been made for the different rates of secretion of the two kidneys; had this been taken into account there might have been a much greater difference. The result, however, shows that the hæmo-renal index of the diseased kidney was below the normal—viz., 1·6 instead of 2—while the index of the healthy kidney was quite up to or even above the normal—namely, 2·4 instead of 2, because it was taking on some of the work of its fellow. No doubt more accurate information as to the salt concentration of the blood could be obtained by separating the serum, but this would be difficult when dealing with the very small quantity of blood and of urine—viz., five cubic millimetres—which is all I require to draw from a patient in order to measure the ratio I have termed the hæmo-renal salt index.

I am, Sirs, yours faithfully,
Edinburgh, Sept. 22nd, 1906. DAWSON F. D. TURNER.

THE PRESENT METHODS OF UTERINE DILATATION.

To the Editors of THE LANCET.

SIRS,—The ordinary student of our recent literature on this subject will at once discard the use of tents in favour of forcible methods. Let us see if this should be so. First, tents are not packed with even ordinary antiseptic precautions, and before use may have been handled by salesmen and would-be purchasers many times. In our text-books their dangers are referred to but no methods suggested of avoiding them. The method I use is to keep the tents in an absolute alcoholic solution of biniodide of mercury (1 in 200). This does not cause them to swell and renders them as safe to leave in the cervical canal as iodoform gauze. In the case of the tent being liable to leave fragments behind, as in sponge tents, the tent should first be wrapped or encased in iodoform gauze by which means none can be left and the gauze being loose laterally allows the tent to fully expand. Should there be a possibly difficult removal owing to constriction at the inner *os* several fine laminaria tents are preferable to one large one. It will then be found much easier to remove them, especially if they are left in 24 hours or more. Instead of using expensive tent introducers the vaginal forceps used by every surgeon will be found most serviceable, for after half an inch or more of the tent has been introduced into the cervix the tent can be released and thrust on by pressure at the end. By this means it will find it own way in a tortuous canal much better than when held rigidly in an ordinary introducer. As a rule tents can be introduced without chloroform or other anæsthetic and the saving of time at the subsequent operation is invaluable. Having watched prominent surgeons trying forcibly to dilate in a short time a rigid *os*, using vulsella to keep down the os whilst Hegars were thrust into it often causing the vulsella to tear their way out, perhaps with a bit of cervix still adherent, I have felt very much in favour of the old tents but used in accordance with up-to-date antiseptics. The vagina can be tightly packed with iodoform gauze after introduction should there be danger of the tents slipping out, but if not I prefer not to pack the vagina at all. I have just removed by the cervix an intrauterine fibroid polypus some three inches in diameter (in pieces), dilatation being procured by tents and gauze previously to operation and the os is now intact and the patient in good health. I could not have had this result by any other method I have seen and the patient was quite run down previously by continuous hæmorrhage, rendering an abdominal operation not desirable to the patient or operator. The best antiseptic solution for keeping instruments in both previously to, and during, operation that I have found is common washing soda and boiled water. The instruments can remain in it indefinitely without injury and are ready for instant use. This does not apply to aluminium, which is injured by soda. I consider that every army corps should have its surgical instruments kept permanently in metal cases full of soda solution. No boiling previously to operation would be necessary.

I am, Sirs, yours faithfully,
THOMAS HODGSON, M.B., Ch.B.
Fitzroy, Victoria, July 21st, 1906.

TYPHOID FEVER AND CANCER.

To the Editors of THE LANCET.

SIRS,—Has there been any case of death from cancer within seven years of an attack of typhoid fever? Is not cancer so extremely rare among typhoid fever cases of recent date, too rare for the age incidence to be a sufficient reason, as to call for an inquiry into something which could *possibly* be a point of connexion between the two diseases? The discovery of any such point of connexion might throw some light on the cause of cancer. Our position as a profession will be indeed singular if we are compelled to admit that cancer abstains from attacking those who have recently suffered from typhoid fever and we are not able to give any reason for it. I am, Sirs, yours faithfully.

WILLIAM ROPER, M.A. Oxon., L.R.C P., L.R.C.S. Edin.
Bridport, Sept. 13th, 1906.

THE PSYCHOLOGY OF THE SELFISH MOTORIST.

To the Editors of THE LANCET.

SIRS,—Your annotation on the above subject in THE LANCET of Sept. 8th misses the true cause of the troubles you suggest as being possibly due to the advent of the automobile—I refer to the dust. Now the dust was on the roads long before the automobile and was stirred up by strong winds and horse traffic, and through the latter became excrement-bearing dust. The roads of England are in much the same condition as they were one hundred years ago and the repairs to the roads—viz , rolling mud into loose stones "to make it bind"—cause in dry weather the blinding dust which is raised by winds and all traffic. Let the new vehicle be taxed judiciously by all means and the proceeds of the tax applied to a modern and dustless method of road-making, then, with the disappearance of horse traffic and the general adoption of the automobile we shall hear no more of "fæcal dust" and dust-borne infections. It must be borne in mind that the automobile is a boon to the medical man both in town and country and has been generally adopted by the profession both in England and abroad, and I think that all our efforts should be directed to the improvement in road-making. The selfish automobilist is with us and always will be, and so is the selfish horse driver, and I always rejoice to see the former punished, but, I regret to say, the latter usually comes off scot free.

I am, Sirs, yours faithfully,
Plymouth, Sept. 18th, 1906. GEORGE F. ALDOUS.

GOATS' MILK FOR INFANTS.

To the Editors of THE LANCET.

SIRS,—With reference to your annotation on the above subject in THE LANCET of August 25th the following quotations from "Climate and Health in Hot Countries," by Lieutenant-Colonel G. M. J. Giles, I.M.S., may be of interest:—

> Goats are extremely hardy and, being naturally clean feeders, require far less attention than cows, while the flavour of their milk in tea is preferred by many to that of cows' milk. They stand marching well, too, and are therefore better suited for use in camp, and as their favourite food is the leaves of bushes they may be trusted to find their living to a great extent as they trot along on their way from camp to camp. Usually their milk agrees excellently with infants, but there can be little doubt that asses' milk is superior for this purpose. (P. 50.)
>
> Goats' milk requires somewhat less dilution than that of the cow and may agree in cases where cows' milk fails. (P. 75.)
>
> Asses' milk is probably the best substitute for an infant's natural food, and failing this goats' milk is to be preferred to that from the cow. (P. 152.)

Such strong expressions of opinion from an officer with almost unrivalled tropical experience should go far to settle the somewhat vexed question of the suitability or otherwise of goats' milk as a food for infants. Since writing my communication on the subject one officer informs me that his child was brought up entirely on goats' milk in the island of Jamaica, a second writer that goats' milk is largely used for in Glasgow, 12 in Edinburgh, eight in Paisley, six in Leith, four in Dundee, and three in Greenock. Of the 11 fatal cases of "fever" seven occurred in Glasgow, two in Dundee, and one each in Edinburgh and Leith; four of the seven in Glasgow, one of the two in Dundee, and the case in Edinburgh were certified as cerebro-spinal meningitis. Of the ten deaths from whooping-cough, seven were returned in Glasgow and two in Aberdeen; and the eight fatal cases of diphtheria included three in Glasgow, and two both in Edinburgh and Aberdeen. Measles also caused three deaths in Glasgow. The deaths in the eight towns referred to diseases of the respiratory organs, including pneumonia, which had been 50 and 58 in the two preceding weeks, further rose to 66 in the week under notice, and exceeded by ten the number returned in the corresponding week of last year. The causes of 19, or 3·4 per cent., of the deaths registered during the week were not certified; the mean proportion of uncertified deaths in the 76 English towns during the same week did not exceed 0·8 per cent.

HEALTH OF DUBLIN.

The annual death-rate in Dublin, which had steadily increased in the seven preceding weeks from 16·8 to 29·4 per 1000, declined to 26·8 during the week ending Sept. 22nd. During the first 12 weeks of the current quarter the death-rate in the city averaged 21·2 per 1000, the mean rate during the same period being only 15·4 in London and 13·0 in Edinburgh. The 195 deaths of Dublin residents during the week under notice showed a decline of 19 from the high number in the previous week, and included 39 which were referred to the principal epidemic diseases, against 52 and 43 in the two preceding weeks; these 39 deaths were equal to an annual rate of 5·4 per 1000, the death-rate during the week from the same diseases being 4·5 in London and only 2·6 in Edinburgh. Of these 39 deaths no fewer than 34 were referred to diarrhœa (against 49 and 39 in the two preceding weeks), two to "fever," one each to measles, scarlet fever, and whooping-cough, and not one either to small-pox or diphtheria. The deaths both of infants and of elderly persons showed a decline from the high numbers in the previous week. Seven inquest cases and five deaths from violence were registered; and 52, or 26·7 per cent., of the deaths occurred in public institutions. The causes of nine, or 4·6 per cent., of the deaths registered during the week were not certified.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointment is notified:—Staff Surgeon A. R. Bankart, lent for three months' study at London Hospital.

ROYAL ARMY MEDICAL CORPS.

Major G. L. Foster, of the Canadian Army Medical Corps, has been attached to the Depôt at Aldershot for a course of instruction. Captain B. Watts is directed to proceed to Fermoy for charge of the Military Families Hospital, vice Captain H. G. Martin. The following officers, now attached to the Aldershot Army Corps, have been selected for service in India:—Lieutenant-Colonel T. J. R. Lucas, C.B., Lieutenant-Colonel H. P. G. Elkington, Lieutenant J. S. Dunne, and Major H. S. Peeke.

ARMY MEDICAL RESERVE OF OFFICERS.

The undermentioned Surgeon-Lieutenants to be Surgeon-Captain:—Robert A. Draper (dated Sept. 14th, 1906) and Reginald O. Gayer (dated Sept. 17th, 1906).

VOLUNTEER CORPS.

Royal Garrison Artillery (Volunteers): 1st West Riding of Yorkshire: John Nightingale (late Captain) to be Surgeon-Captain (dated Jan. 20th, 1906).

Rifle: 2nd Volunteer Battalion the King's Liverpool Regiment: William Henry Broad to be Surgeon-Lieutenant (dated Sept. 22nd, 1906). 3rd Volunteer Battalion the Lancashire Fusiliers: Wilfred Moritz Steinthal, late Captain, Northern Command, Manchester Companies, Royal Army Medical Corps (Volunteers), to be Surgeon-Captain (dated Sept. 22nd, 1906).

ROYAL ARMY MEDICAL CORPS (VOLUNTEERS).

Lancaster and Border Bearer Company: Captain W. B. Cockill to be Major (dated Sept. 22nd, 1906).

DEATHS IN THE SERVICES.

Major Thomas Birt, R.A.M.C., on Sept. 19th at Reading. He entered the service in 1887 and served with the Chitral Relief Force under Sir Robert Low in 1895 (medal with clasp). He was promoted to major in 1899.

Surgeon Herbert Bartlett Simpson, R.N., recently at Ceylon from enteric fever. The deceased officer, who was only in his twenty-ninth year, had served for some time at the Royal Naval Hospital, Stonehouse (Plymouth).

FRESH MEAT IN THE NAVY.

The determination has been arrived at by the Admiralty to slaughter pigs at the Royal William Victualling Yard, Stonehouse (Plymouth), for the supply of fresh pork to ships in the port. Pens and slaughter-houses and all the appurtenances are to be erected in the yard for this purpose. The pigs will be supplied by contract but the slaughtering will be done under official supervision. The Admiralty has also called for a report on the best means of supplying victuals to ships within reasonable distance of the port of Plymouth.

EXPENDITURE OF ARMY ALLOWANCES IN INDIA.

Lord Kitchener has issued an order dealing with military expenditure, in which he points out that heavy waste of the public funds occurs through officers of all ranks spending budget allotments at a forced pace towards the end of each financial year in order to prevent the allotments from lapsing. The Commander-in-Chief forbids this hurried squandering of unspent balances.

Correspondence.

"Audi alteram partem."

THE ELECTRICAL RESISTANCE OF THE BLOOD AND URINE AS A TEST OF THE FUNCTIONAL EFFICIENCY OF THE KIDNEY.

To the Editors of THE LANCET.

SIRS,—I am grateful to Mr. T. M. Wilson for calling my attention in THE LANCET of Sept. 8th, p. 682, to the fact that the electrical resistance of the blood does not depend solely upon the salts present, but also upon the proportion of the total volume of the blood which is occupied by corpuscles. I was, of course, aware from experiments made by me on artificial urines prior to 1892[1] that the presence of non-electrolytes such as sugar and albumin would slightly increase the resistance, but this effect can for practical clinical purposes be disregarded in the presence of the dominating influence of the salts. I must also express my thanks to Mr. Wilson for drawing my attention to his conductivity measurements and freezing-point observations on blood and serum in pernicious anæmia and other diseases. He confirms, I am pleased to see, the observation I made a number of years ago[2] as to the increased conductivity of the blood in pernicious anæmia, but he disagrees with me as to the cause. Whether this increased conductivity be due to the diminution in the corpuscles, or to the increase in the salts, or to both, it is of importance in throwing light on the pathology of the disease.

Much more, however, can be learned as to the renal efficiency by ascertaining the ratio which I have termed "the hæmo-renal salt index"—namely, by comparing the electrical resistance of the blood of a patient to the electrical resistance of his urine, taken at one and the same time. Thus, in pernicious anæmia the index is only a fraction of what it is in health, due to the diminished resistance of the blood and the increased resistance of the urine. Dr. F. G. Hopkins[3] found a marked diminution in the salts of the urine in five cases of pernicious anæmia. But it will be chiefly in surgical affections of the kidney that the method will be in combination with cryoscopy of use in ascertaining the renal capacity. I append the notes of a case under the care of Dr. H. Alexis Thomson of tuberculous kidney; the secretions were examined for me by Dr. A. C. T. Woodward. The resistance of the blood was very high and amounted

THE GIBRALTAR WATER-SUPPLY.

(FROM OUR SPECIAL SANITARY COMMISSIONER.)

AFTER the Fourteenth International Congress of Medicine held at Madrid in 1903 I managed to visit both Gibraltar and Tangier. When a few months ago the Fifteenth International Congress of Medicine met at Lisbon I again profited by the comparative proximity to contemplate once more what the ancients described as the pillars of Hercules The interest that both these places excite is unfailing though of so different a nature. For Gibraltar the British patriot feels the full glow of pride, though the last time I was there I met a German officer who was making a pilgrimage to the great fortress to see the place where, as he put it, Hanoverian regiments had immortalised themselves in defending this possession of their Hanoverian king. For my part, I view with no less pride the victories won at Gibraltar by the science of hygiene in the saving of human life. During the ten years 1881–90 the average annual death-rate was 23·0 per 1000 of the population. During the next ten years the annual average was 20·65 per 1000. From 1881–90 the average annual "zymotic" death-rate was 4·93 per 1000 and from 1891 to 1900 it had fallen to 2·79 per 1000. In former days Gibraltar was subject to terrible epidemics and in 1804 no less than 5733 persons died from fever in a few weeks out of a population of about 15,000. On the other hand, in 1885, when the terrible cholera epidemic devastated the surrounding country and in spite of the fact that thousands of Spanish labourers and others came into Gibraltar to work for the day, returning to Spain at sunset, there were only 34 cases and 25 deaths from cholera at Gibraltar.

The census of 1901 showed that the population of Gibraltar then numbered 27,460, including 6475 soldiers But to this must be added a large amount of shipping and a great number of passengers who land, some only for a few hours, others for a few days. This, especially the shipping, increases the greatest difficulty that besets the fortress and town of Gibraltar. Considering that Gibraltar is a precipitous limestone rock jutting out into the sea there can be no natural water-supply. There are wells certainly at the foot of the perpendicular cliff which constitutes the most formidable feature of the North Front. The moment, however, any quantity of fresh water is drawn from these wells it is replaced by the salt water that comes filtering in from the sea which is so near on both sides of this narrow peninsula. Nevertheless, and though this water is brackish, it has very greatly contributed to preserve the health of the town. It is not fit to drink but it has rendered the creation of a system of drainage possible. Triple expansion engines have been placed at the North Front. These pump up some 200 000,000 gallons of this water to an altitude of 250 feet into reservoirs near the old Moorish Castle and to some other minor reservoirs on the Europa road. At the latter point another pump raises a portion of this water to a height of 535 feet. By these means it has been possible to lay mains and to deliver by gravitation water to all the dwellings at Gibraltar. This water is too salt to drink but it provides ample means for flushing house drains and public sewers, for watering and cleansing streets and yards, and for extinguishing fires. It is called the sanitary supply and great has been the service it has rendered to the cause of sanitation.

Till 1868 the inhabitants had no other water to drink than the rain water collected for the most part on the roofs of the houses. Well digging was not successful: if the water was not brackish it was often impure. The rainfall, however, is uncertain and when water is most needed there is no rain. In summer the heat is more oppressive than might be imagined by the mere reading of the thermometer. This is due to the stagnation of the air resulting from the shelter which the high rock affords. Yet in winter the north wind, which fortunately is very rare, brings from the snow-clad mountains biting cold. Though snow is almost unknown, there are hail storms. From 1790 to 1901, during 111 years that a record has been kept, the average annual rainfall has been 33·33 inches. The most rainy months were November with an average of 5·70 inches, and December with 5·57 inches. Then follow January, February, and March. Barely half an inch falls in June, July, and August, while in May and September the rainfall is under two inches. The highest fall in one day was on Dec. 14th, 1796, when it amounted to 9·13 inches. The highest record for rain during an entire year was that of 1855–56, when 77·14 inches fell; the lowest was in 1800–01 when only 15·12 inches of rain were recorded. It will be seen by these figures that it is a hazardous matter to depend upon the rainfall for a water-supply. During 1884, however, in the Southport Ditch, near the Ragged Staff, condensing machinery, which, if I remember correctly, had been used during the Abyssinian campaign, was erected. These condensers could distil 650 000 gallons of salt water per month. The water thus freed from salt and sold for drinking purposes to the inhabitants was of help in keeping the cholera at bay during the great epidemic which occurred in the following year.

Shortly after this first attempt on a large scale to secure a public supply of drinking water efforts were made to collect water on the slope of the rock. In 1898 an area of 14½ acres was especially prepared for this purpose. The fissures and indentations in the rock were filled up and the surface was concreted so as to make a clean, smooth catchment ground. Then great reservoirs were dug deep into the rock and so far within the mountain as to be not only bomb proof but at such a distance from the surface as to assure that the water should remain at the same temperature whatever outside variations may occur Here the water is preserved underground, as in nature, only at a higher level, so that it can be distributed to the habitations below by the force of gravitation. The reservoirs thus built have a capacity of 5 000,000 gallons. These I visited and described after the Madrid Congress of 1903 There are four reservoirs, each holding 1 250,000 gallons, so that while the water is being taken from one it is allowed to settle in the others. When these great works were first undertaken the question was raised as to whether it would be possible to sell the water. To-day the complaint is made that the water sells too readily, that the demand is so great that the inhabitants cannot get what they urgently need.

The result was that a much larger scheme was prepared by Mr. William Wallace Copland, the secretary and engineer of the Sanitary Commissioners. This scheme I fully described three years ago, but to-day the tunnel is completed and I was able to go right through in a little truck on rails which, entering near the Moorish Castle and emerging high above Catalan Bay, seemed to pierce the rock like a needle. A smooth sand-slide that slopes from the rock above Catalan Bay, that is, on the Mediterranean side, has, to the extent of 40 acres, been covered over with corrugated iron and forms a splendid catchment ground for rain water. But a tunnel had to be pierced so as to convey this water over to the Atlantic side of the rock, where Gibraltar is situated. The tunnel is really a wonderful construction. It has been pierced 20 feet above the reservoirs; it is seven feet high and ten feet broad. On one side there is a passage three feet broad with a rail so that trucks can be wheeled through from end to end. The remaining seven feet in the width hold an open channel or culvert where the water passes but over which it could flow in case of storm pressure. About half-way across there is a mysterious cavernous opening which seems to descend into the very centre and down to the bottom of the rock. On one occasion 5 000,000 gallons of water were poured into this opening and disappeared. Doubtless the water reached the sea but no one knows how. The extraordinary feature about the rock is that it contains no fossils whatsoever. Though it consists of the Jurassic limestone formation there are no fossils. If any existed they certainly would have been found during the piercing of the tunnel through the centre of the rock. Beside, a great many of the stones extracted were broken up for roads and a reward was offered to the labourers if they could find a fossil. Nor is there anything to indicate the age of the rock. Geologists are at a loss to explain this absence of fossils. Another curious point is that the monkeys who inhabit the higher portions of the rock conceived a strong dislike to the catchment ground; therefore, they occasionally arm themselves with great stones, climb to a vantage ground as high above the place as possible, and, by hurling these stones upon the corrugated iron, have succeeded in making several holes. As the rain-water runs through these holes and is lost in the sand which the iron sheeting is meant to cover, it is necessary constantly to mend these damaged portions of the catchment grounds. Perhaps the monkeys find that they cannot run across the corrugated iron plates as easily as over the sand. Gibraltar has been attacked by feeding infants at Gibraltar, and the wife of a third gentleman tells me that her eldest son was fed entirely on goats' milk while in India as cows' milk did not agree with him.

Personally I am strongly of Colonel Giles's opinion that the milk of a "clean feeder" is much more desirable than that of an animal which occasionally finds its nutriment in village rubbish heaps. If Indian mothers realised that "when pressed by hunger there is no fouler feeder than a cow, and it is a dismal fact that, in the polity of an Indian village, the cattle rival the pigs in their efficiency as scavengers," they would, when travelling about and unable to keep a cow of their own, prefer the milk of the goat to that of the cow as food for their infants.

I am collecting opinions from my colleagues with tropical experience and making a few experiments and hope to submit a report later, but in the meantime I would esteem it a favour if the readers of this journal would favour us with their views on this very important detail of infant hygiene.

I am, Sirs, yours faithfully,

WHAT IS A SPECIALIST?

To the Editors of THE LANCET.

SIRS,—In the days when Imperial Liberalism was a political factor I remember a discursive speaker being described as one who could talk on everything, "from Rosebery and current topics to raspberry-and currant tart" Some of your correspondents have shown similar discursiveness, and I use this as an excuse for introducing some new facts to the notice of the medical public which may not seem strictly germane to the present discussion. It may be added, however, that when the subject of a correspondence is the search for a definition there can be no certain limits to the matters dealt with.

The word "specialist" is used by some of the public and by most medical men to imply a man who has special knowledge of some very distinct branch of medicine and surgery, and to obtain this knowledge he must possess very distinct opportunities. Thus a man can be called a specialist who has unusual opportunities for observing and treating diseases of the eye or the ear, of the throat or the nose. Apparatus is designed to help him in diagnosis the full utility of which can only be obtained in practised hands, or estimated by practised observation. He must have many patients before he can acquire familiarity with the particular points of his specialty, and, roughly speaking, he can only get his material by being attached to a hospital. This fact has unfortunately led many members of the public to suppose that being attached to a hospital and being a specialist are synonymous terms. A letter in your issue of Sept. 8th, p. 678, from Dr. Francis Hawkins shows that he shares this opinion, and he is probably not alone among consulting medical men. In this view only one class of medical man should attain to the rank of a hospital surgeon or a hospital physician, and it will be the duty of those members of the medical profession who are in a lower sphere to feed this superior class, sending them all cases the treatment of which is not perfunctory, and inviting their aid at all operations which would not fall naturally within the scope of a house surgeon. What I want to bring out is this. Firstly the general practitioner, in the ordinary course of his duties, will not become a specialist—say—in diseases of the ear. He will not see enough aural cases to enable him to group them into divisions and subdivisions for purposes of diagnosis and prognosis; he need not pretend to have familiarity with delicate operative procedures. But, secondly, he will see enough cases of pneumonia, of pathological developments following zymotics, or of complicated labours to give him a special knowledge in such situations, if he spends a special amount of time pondering the natural and other phenomena and brings a special amount of intelligence and investigating method to bear upon the symptoms. Such an expert general practitioner may be just as much possessed of individual and particular knowledge as the physician-anæsthetist or the ophthalmic surgeon to a hospital. Therefore, I can see no reason whatever why he should not assume, when he chooses, the position of specialist or consultant. If the members of the public go straight to him no harm will be done, for he is a practically learned man; on the other hand, his colleagues, especially those junior to him in the general ranks of the profession, might often like to consult one possessing this valuable and hardly earned kind of experience.

The interesting correspondence which has been running in your columns under this heading was started, if I remember rightly, by the question whether a general practitioner, desiring to pass into consultant or specialist ranks, could indicate the same in any way on his door-plate. The question has not been answered, but I do not see why he should not be allowed to do so.

I am, Sirs, yours faithfully,
M.B., B.C.

THE VACANCY ON THE SENATE OF THE UNIVERSITY OF LONDON.

To the Editors of THE LANCET.

SIRS,—In a short time members of Convocation of th University of London will receive voting papers for th election of a senator. There is now an excellent opportunit for graduates to show their disapprobation of the methods b which it is sought to increase the number of men who hol the degrees of the University. The rational method o obtaining this end would be to increase the efficiency of th teaching so that the border line man would find himself o the right side of the pass-list; the actual method adopte has been to reduce the stringency of the examinations. Th reason is not far to seek. London medical schools have fel severely the competition of the provincial schools and hav conceived the idea of attracting more students by the lure o an easily obtainable degree at the University. They ar aware that in the provinces the London degrees are held i great estimation but they are unable to realise that th cheapening of the degree is accompanied by a correspondin drop in value in the eyes of the men whom they woul attract. I say nothing of the breach of faith with those o us who took the degrees before the *débâcle* That is sufficiently rankling to need no spur at the present time.

Now of the candidates for the seat on the Senate D Graham Little is frankly and freely hostile to the policy th would reduce our degree to the level of the second rate. D Frederick Taylor, on the other hand, approves of the actio of the Senate in the recent changes and, what is mo significant, is supported by many of the teaching staff o the London schools. We want no more tinkering wit our degrees. The futile juggling with "internal" an "external" students revealed to many the hopeless chaotic state into which the governing minds had drifte at the time of the great change. As an instance, I wa registered as an internal student of medicine the year befo I took my M.D. On receiving notice that I was receive a certificate for that degree as "an extern student" I wrote to say that I was registered as "internal" student, so that the classification was wron In reply I was told that the distinction into the two class had not existed long enough to enable a student to take h doctorate "internally" and therefore I was external. T delightful clearness of this bit of reasoning led me to wri again saying that I did not want either their internal external certificate. I wanted the old certificate of t University of London. But I did not get it. I received "internal" certificate after all. But a fellow M.D. of t same hospital, the same year, and passing the same tim had to accept an external paper.

Let us return Dr. Graham Little to the Senate and follow it up by selecting similar men for each succeeding vacancy. Enough mischief has already been done to our famous university.

I am, Sirs, yours faithfully,
M.D. LOND.
Sept. 24th, 1906.

HOSPITAL FOR SICK CHILDREN, GREAT ORMOND-STREET, LONDON.—The winter session of lectures and demonstrations at this hospital will commence on Oct. 4th at 4 P.M. and will be continued on succeeding Thursday afternoons at the same hour. The lectures are free to medical practitioners. The opening lecture will be given by Dr. A. E Garrod on Some General Considerations of Disease as it Occurs in Children, and on Oct. 11th Dr. T. Thompson will lecture on Juvenile Asthma and its Treatment. Inquiries respecting these lectures should be addressed to the dean of the medical classes at the hospital, Dr. A. F. Voelcker.

THE GIBRALTAR WATER-SUPPLY.

(FROM OUR SPECIAL SANITARY COMMISSIONER.)

AFTER the Fourteenth International Congress of Medicine held at Madrid in 1903 I managed to visit both Gibraltar and Tangier. When a few months ago the Fifteenth International Congress of Medicine met at Lisbon I again profited by the comparative proximity to contemplate once more what the ancients described as the pillars of Hercules The interest that both these places excite is unfailing though of so different a nature. For Gibraltar the British patriot feels the full glow of pride, though the last time I was there I met a German officer who was making a pilgrimage to the great fortress to see the place where, as he put it, Hanoverian regiments had immortalised themselves in defending this possession of their Hanoverian king. For my part, I view with no less pride the victories won at Gibraltar by the science of hygiene in the saving of human life. During the ten years 1881–90 the average annual death-rate was 23 0 per 1000 of the population. During the next ten years the annual average was 20·65 per 1000. From 1881–90 the average annual "zymotic" death-rate was 4·93 per 1000 and from 1891 to 1900 it had fallen to 2·79 per 1000. In former days Gibraltar was subject to terrible epidemics and in 1804 no less than 5733 persons died from fever in a few weeks out of a population of about 15,000. On the other hand, in 1885, when the terrible cholera epidemic devastated the surrounding country and in spite of the fact that thousands of Spanish labourers and others came into Gibraltar to work for the day, returning to Spain at sunset, there were only 34 cases and 25 deaths from cholera at Gibraltar.

The census of 1901 showed that the population of Gibraltar then numbered 27,460, including 6475 soldiers But to this must be added a large amount of shipping and a great number of passengers who land, some only for a few hours, others for a few days. This, especially the shipping, increases the greatest difficulty that besets the fortress and town of Gibraltar. Considering that Gibraltar is a precipitous limestone rock jutting out into the sea there can be no natural water-supply. There are wells certainly at the foot of the perpendicular cliff which constitutes the most formidable feature of the North Front. The moment, however, any quantity of fresh water is drawn from these wells it is replaced by the salt water that comes filtering in from the sea which is so near on both sides of this narrow peninsula. Nevertheless, and though this water is brackish, it has very greatly contributed to preserve the health of the town. It is not fit to drink but it has rendered the creation of a system of drainage possible. Triple expansion engines have been placed at the North Front. These pump up some 200 000,000 gallons of this water to an altitude of 250 feet into reservoirs near the old Moorish Castle and to some other minor reservoirs on the Europa road. At the latter point another pump raises a portion of this water to a height of 535 feet. By these means it has been possible to lay mains and to deliver by gravitation water to all the dwellings at Gibraltar. This water is too salt to drink but it provides ample means for flushing house drains and public sewers, for watering and cleansing streets and yards, and for extinguishing fires. It is called the sanitary supply and great has been the service it has rendered to the cause of sanitation.

Till 1853 the inhabitants had no other water to drink than the rain water collected for the most part on the roofs of the houses. Well digging was not successful; if the water was not brackish it was often impure. The rainfall, however, is uncertain and when water is most needed there is no rain. In summer the heat is more oppressive than might be imagined by the mere reading of the thermometer. This is due to the stagnation of the air resulting from the shelter which the high rock affords. Yet in winter the north wind, which fortunately is very rare, brings from the snow-clad mountains biting cold. Though snow is almost unknown, there are hail storms. From 1790 to 1901, during 111 years that a record has been kept, the average annual rainfall has been 33 33 inches. Let us return Dr. Graham Little to the Senate and follow it up by selecting similar men for each succeeding vacancy. Enough mischief has already been done to our famous university.

I am, Sirs, yours faithfully.

Sept. 24th, 1906. M.D. LOND.

HOSPITAL FOR SICK CHILDREN, GREAT ORMOND-STREET, LONDON.—The winter session of lectures and demonstrations at this hospital will commence on Oct. 4th at 4 P.M. and will be continued on succeeding Thursday afternoons at the same hour. The lectures are free to medical practitioners. The opening lecture will be given by Dr. A. E. Garrod on Some General Considerations of Disease as it Occurs in Children, and on Oct. 11th Dr. T. Thompson will lecture on Juvenile Asthma and its Treatment. Inquiries respecting these lectures should be addressed to the dean of the medical classes at the hospital, Dr. A. F. Voelcl

For subcutaneous injections amber-glass ampullæ of quinine lactate in isotonic solution are recommended as being those which give the best results with the least discomfort. Incidentally it may be remarked that the diaphoretic action of whisky is insisted upon here, as compared with the action of cognac. British physiological chemists might well try to solve this problem. It may well be that the enormous quantities of whisky which are exported to our possessions beyond seas may be found to be, good and bad alike, more deleterious than even the teetotalers imagine.

The excellent collection of specimens, macro- and microscopic, is yearly being added to and as much as possible is done in the way of instruction by means of the epidiascope The teachers could not be more painstaking with the students, each taking a pride in making the sometimes very abstruse problems clear to all and grudging no pains and time to do this. To German thoroughness cosmopolitan *savoir faire* is added—the result being all that can be desired from the student's point of view. The extraordinarily small fee—£5—charged for the instruction afforded, with all equipment for practical work, deserves imitation in more ambitious centres.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

The Care of Lunatics.

IN these days of high rates and constantly increasing expenditure it is *an encouragement to hard-pressed ratepayers* to discover any indication, if only from its novelty, of a wish on the part of a public body to use care and discrimination in the spending of public money. Whether lunacy is increasing or not, there is no question of the heavy burden which the care and maintenance of pauper lunatics place on the ratepayers of Lancashire. At a meeting of the Prestwich (North Manchester) guardians on Sept. 20th a letter was read from the clerk of the Lancashire asylums board inviting the chairman, the chairman of the workhouse committee, and the clerk of the Prestwich guardians, to a conference with a special committee of the Lancashire asylums board to be held at Preston on Sept. 27th. The subject to be discussed is whether it may be possible "by a closer coöperation between the asylums board and the boards of guardians in the county to reduce the cost of the maintenance of pauper lunatics to the ratepayers." It is said that about three-fourths of the certified lunatics are kept in the asylums, and one-fourth in the workhouses. It is possible that with more careful classification this proportion might be altered without disadvantage to the inmates of either and to the relief of the congested asylums. Some of those in the workhouses ought to be in the asylums if only there were room for them, while many chronic and harmless inmates of the asylums might be quite well cared for in the workhouses. One of the matters to be considered is whether in order to accommodate the harmless class of lunatics "an extension of the workhouse accommodation should be made or some separate accommodation for them provided in close connexion with the asylums." The asylums board does not suggest, nor it is said does it intend to suggest, "that the financial responsibility with regard to lunatics properly falling upon them and upon the county generally should be transferred to the boards of guardians and to the individual unions." However this may be arranged, the chief interest to the ratepayers is that the great weight of the maintenance of paupers—sane and insane, able-bodied or ailing—is beginning to be perceived by those who control expenditure and there is a prospect of an effort, without harshness or injustice, to be careful and not lavish. The Prestwich board decided to accept the invitation.

School Children's Sight.

Dr. A. Brown Ritchie, medical officer to the Manchester education committee, states in a report on defective eyesight in city school children that there are 85 children in the municipal schools with defective vision "of such a degree as to warrant special educational treatment which could not be given in the ordinary classes of a public elementary school." He will not have the figures from the non-provided schools till the end of the year. There are a considerable number of children with grave defects of eyesight not provided with glasses. This is very much the fault of the parents who in many cases are too indifferent to the welfare of their children or too ignorant to trouble themselves much about it. There is a subscription fund from which the children of very poor persons can be fitted with spectacles, if the parents will take a little necessary preliminary trouble "but, unhappily, they will not always exert themselves to this extent to preserve their children's eyesight." It is to be feared that this statement is applicable to others than the "submerged" of the labouring classes.

Rochdale Infirmary Memorial.

The Rochdale people are evidently in earnest as to their decision to extend the infirmary as a memorial of the jubilee. Several of the cotton-spinning companies are contributing to the fund required. The Rochdale Provident Coöperative Society is giving £1000 to commemorate the jubilee. The sum of £500 is to be given to the infirmary, a drinking fountain is to be placed in Broadfield Park, and the balance is to go to the Nurses' Home.

Vaccination Exemptions.

The Heywood magistrates continue to have a busy time in giving certificates of exemption to antivaccinationists. On one day about a week ago 19 were issued. Only five of the applicants were from Heywood itself, the remainder being from a wide area of Lancashire and Cheshire, Manchester itself sharing in this scheme for insuring the spread of small-pox. The ignorance, and in many cases the sheer and absolute fanaticism, displayed are somewhat depressing and seem to show that mental decadence is accompanying the physical deterioration unquestionably affecting some sections of the population. It is cheering, therefore, to find that at Bury, not very far from Heywood, the magistrates have refused to reduce the price of exemption certificates from 2*s*. to 1*s*. as they were requested to do by a local anti-compulsory-vaccination society. The scale of fees is approved by the Bury town council and sanctioned by the Home Secretary.

Sanitary Inspectors' Conference.

The Conference of the Sanitary Inspectors' Association, presided over by Sir J. Crichton-Browne with his usual ability, has been marked by very useful papers and discussions on sanitary matters. Mr. West, chairman of the executive council, drew attention to a principle not always kept in mind which is equivalent to the old axiom that prevention is better than cure. He thought that there was a tendency to give too much consideration to the "contagious particle," the seed, or germ, and too little to the soil in which it had to develop its brood. It seemed to be considered necessary to find "disease-producing organisms" in cockles and oysters before insisting that the water where they lived should be free from filth and, as at Lincoln, to prove the existence of typhoid germs in a water-supply "by means of the ravages of an epidemic before the central authority in the land found it necessary to insist on the provision of a pure water-supply." Though desirable and always to be aimed at, the discovery and elimination of typhoid germs from a water-supply into which they have entered by some unobserved leakage before an epidemic threatens are by no means easy, the epidemic itself being in many cases the first thing that casts suspicion as to the water being its cause. But apart from the loss of life and the misery and distress wrought by such an illness as typhoid fever it would be worth while on the lower ground of economy to keep up a constant watch and the necessary examinations, for the cost would certainly be less than was that of an occasional outbreak of disease.

Sept. 25th.

WALES AND WESTERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENTS.)

Glamorgan Water supply.

THE Glamorgan county council obtained in the present session of Parliament an Act enabling surveys to be made to ascertain the amount of water available for the supply of the inhabitants of the county. A further step was taken at the last meeting of the council when a solicitor was appointed to make a summary of the powers and obligations of the several Water Acts of boroughs, district councils, and water companies authorised to supply any part of the county. At the many foes but this is its first experience of a bombardment at the hand of a small but agile force of monkeys.

Though the tunnel is now completed the water difficulty is not yet solved. Enough, and more than enough, water can be obtained, but there is not sufficient storage room for this water. The scheme comprises reservoirs to a capacity of 17,000,000 gallons; then another 30 acres can be added to the catchment grounds and the water difficulty will be at an end for ever. Till this is done the authorities dare not encourage the consumption of their new town supply. The Mediterranean Club, all the soda-water manufactories, the shipping, and the various industries get their water directly from the main supplied by the rain collected on the rock and stored in the great reservoirs. But there is a danger that the 5,000,000 gallons which these reservoirs contain may not suffice during a very dry season. The inhabitants who subscribe are given a water meter and pay for every 100 gallons which they consume. In some 500 houses at Gibraltar the water collected on the roofs is no longer drunk, but some of these inhabitants drink the town supply which they take in jugs from a public fountain. Also it can be taken to their houses and sold to them from a water-cart, or when the house is near enough to a water main their cisterns can be filled by means of a hose. This latter, when practicable, is the easiest and cheapest method. To increase the supply of pure water available pending the construction of further reservoirs the condensers which were used for the Boer prisoners at Bermuda have been purchased and will be put up at Gibraltar. In the meanwhile the sanitary authority has to keep a very keen watch over the roofs and the cisterns of the houses. These must be thoroughly cleaned at least once a year. Then if the water is befouled it only affects one household. The same system, the gathering and storing of rain water from the roof for drinking purposes, prevails largely in Spain but it is not so strictly regulated. Of course this is a soft water, but I could not find that any complaints had been made as to its effects on metallic cooking utensils or on the people who drank it. On the other hand, it is notorious that crews of ships who have to drink condensed sea water soon suffer. In regard to the rock catchment water, it must be noted that before reaching the reservoirs it goes through a rough filter of large stones which retains the larger objects that float down with the water. Then it is more carefully filtered through polarite and also aerated by falling some 40 feet in a thin sheet or spray which forms a sort of cascade. All this must make some alteration in the quality of the water which doubtless takes up a slight quantity of mineral matter, so that it is no longer pure rain water, which, if considered merely as distilled water, might be injurious when drunk in large quantities. Thus, and as matters now stand, there is still a risk that the water-supply may prove insufficient during a very dry season. On the other hand, the water is free from organic contamination and can be drunk with impunity. Dr. W. Turner, surgeon to the colonial hospital and civil prison, informed me that he barely saw more than a dozen cases of typhoid fever in the course of the year, and of these at least half came from ships and were not inhabitants of Gibraltar. What now remains to be done is simply to enlarge the capacity of the reservoirs. Then with the vast catchment grounds on the Catalan Bay side, the tunnel to bring the water collected there over to the Gibraltar side, and reservoirs large enough to keep a sufficient reserve, the great fortress will be safe and able to face every emergency.

THE INSTITUTE FOR TROPICAL HYGIENE IN HAMBURG.

(FROM A CORRESPONDENT.)

HAMBURG, which owes so much to the sea, has done its best for the seaman. Alongside the splendid Seamen's Hospital, and in direct connexion with it, stands the institute for the study of the diseases which are incidental to life at sea and in the tropics, an institute which, although it has been for so few years in existence, has done a great deal to further our knowledge of the many and vast economic problems which, it is now recognised, arise from the heritage of the white man in the tropics. Under the direction of Professor Nocht, with the collaboration of Staff-Surgeon Fülleborn, Dr. Otto, Dr. Viereck, Dr. Mayer, and Mr. Giemsa, there is given a thoroughly solid instruction in the methods to be adopted in elucidating these problems. As Hamburg had honoured itself by honouring Fritz Schaudinn, the great protozoologist whose too early death leaves a gap which it will be hard to fill, so the institute honours itself by giving attention to the many facts of protozoology on which light was shed by the labours of Schaudinn, labours which may be imitated but can hardly be equalled by any of his successors. The importation of babesia parva, the cause of "coast fever," into East Africa may have far-reaching results; the presence of trypanosoma Gambiense is ruining Uganda; and as we have the stegomyia and the other necessary conditions for the life of the parasite of yellow fever already in India the opening of the Panama Canal will probably lead Great Britain to take great interest in the development of that parasite. India has for long been the home of cholera and for some years the home of plague; will she form the home of Yellow Jack? This is a question for those who busy themselves with lowly forms of life to answer. And these lowly forms are of interest other than medical: the history of the development of a trypanosoma throws light on Weismann's once-scoffed-at theory and might well give pause to those who hold that natural needs can be modified by education. Here, too, is a rich field for those who love to twist facts to suit the theory of the equality of the sexes—a field in which the workers are as yet but few.

In the Seamen's Hospital the treatment received has to be paid for—a fact which, unusual as it is in Britain, has caused many a British sailor to be taken away when the captain could not see the immediate need for treatment, as in the early stage of typhoid fever, or knew not whence the money was to be got to pay for the case. Surely here is an opportunity for some philanthropist who has at heart the immense importance of our merchant service to do a good turn to Jack Tar by endowing half a dozen beds in this hospital for British seamen. In the wards may be seen cases of typhoid fever, a disease from which Hamburg would be free, thanks to its excellent water-supply, were it not imported by seamen and others. After careful study of all methods of treatment that by baths and diet has come to be adopted with excellent results. There are cases in the various stages of beri-beri, a disease which, whatever the bacteriologists may say, has more than an accidental connexion with the want of a proper meat diet; cases of helminthiasis, among whom one may see those which present the profound anæmia caused by the bothriocephalus latus, an anæmia which is due certainly to the demands made on the organism of the host and also, it may be, to a profound change in the bone-marrow cells, caused by toxin excreted by the parasite. The cases of dysentery are mostly of the amœboid form and it is found that the mistura simarubæ cum cortice radicis granati, recommended by Gräser, is of great service in these cases. Enemata are also much used and consist of a 1–2 per 1000 solution of tannic acid, of which from half to one litre is given at a time. I was glad to see that much stress is laid on dieting by means of raw meat. For years we have in India adopted this means of nourishing the patient whenever no religious prejudices stood in the way and have found that it is much less irritating to the bowel than milk, which is mostly excreted as firm curd.

Of malaria the cases are many. In one case all three forms of the parasite—quartan, tertian, and tropical—have been observed, a fact which may interest those who hold with Laveran that all are but modifications due to external influences. The treatment is briefly one gramme of quinine hydrochlorate, divided into five doses, in the 24 hours; it has been found that larger doses at a time are liable to cause symptoms of blackwater fever in the African cases. For these when they can take only a small dose a system of dosage is pursued by which the organism becomes habituated to the drug and finally is able to absorb with benefit quantities which at first would have caused very untoward results. With true German thoroughness all sides of the question have been studied and the use of sugar-coated tablets is condemned, as the coating becomes very hard in a short time. Capsules, easy of dissolution in water and accurate in dosage, such as those prepared in Frankfort, may be recommended. Those who have seen the "quinine pills," as hard as B B shot, which used to be the stock in Indian dispensaries, will appreciate the importance of this small matter.

same time the county medical officer of health was instructed to obtain statistics of the quantity and quality of the existing supplies and of the probable deficiencies of such sources for the growing population. The reports of these officials will be laid before a conference which is to be held at Neath on Oct. 8th, when representatives from the corporations of Cardiff, Swansea, and Merthyr and from the district councils in the county will consider the best means of utilising the existing sources of water-supply and of obtaining others.

A Pauper Register.

A communication has been sent from the Local Government Board to boards of guardians in England and Wales requesting that a register may be kept by the clerks to the guardians of every person relieved during next year whether in the workhouse or as an outdoor pauper. The form of register suggested by the Board includes, in addition to the names, age, and occupation of the person relieved, a record of the dates between which he has been receiving relief, the form of relief, and the reason for its discontinuance. A yearly summary will give the total length of time during which the person has been chargeable and the number of times he has been relieved during the year. The information to be obtained from these records ought to be extremely valuable but if it is to be trustworthy it is necessary that strict accuracy should be insured. The clerk to the Cardiff board of guardians has stated that it will be impossible to keep the register without extra clerical assistance and the guardians have asked the Local Government Board whether the expense involved will be borne by the Imperial funds. There are about 6000 paupers in Cardiff and it is thought that the work of keeping the register would employ nearly the whole of the time of one clerk.

Bristol Municipal Lodging House.

Some of the members of the health committee of the Bristol corporation are concerned that the newly established municipal lodging house is not already paying its way. There is accommodation for 120 men and the general arrangement and administration are on the lines of similar undertakings at Croydon, Southampton, Salford, and elsewhere. The cost of the Bristol house was just over £10,000, of which sum £1600 were for land and £1000 for furnishing. The accounts for the year ending March 25th, 1906, show a total loss of £846, or if the repayment of loans and interest is excluded of £260. The charge made to each lodger is 6*d.* per night. To those who are familiar with the conditions of many common lodging houses in our large towns a mere money loss upon the maintenance of a cleanly, well-ventilated, and properly conducted municipal lodging house will not be regarded as a real loss. There must be some gain to the community in the increased self-respect of the lodgers, even if we leave out of consideration the physical gain which must accrue to them through their more satisfactory surroundings. It is to be hoped, therefore, that the city council will not be disheartened with the result of the first year's working of its lodging-house and will not accept the suggestion of some members to sell or to let the buildings.

The Dolgelly Urban Council and Isolation.

At a meeting of the Dolgelly urban council, North Wales, on Sept. 21st the medical officer, Dr. Hugh Jones, reported that the scarlet fever epidemic had apparently come to an end and the general health of the district was most satisfactory. Mrs. Vaughan, who made an offer some months ago of a free gift of land for the erection of an isolation hospital, wrote to him that the council must come to a decision before Sept. 29th. She felt that the council had had ample time to consider the matter. She made the further condition to her offer that a reasonable scale of charges should be drawn out for the reception of patients from a few neighbouring parishes. The medical officer said that the offer could not fail to be an inestimable boon to the town and district for many generations. The rural district council, which had agreed to contribute one-third of the cost, wrote that it had rescinded that resolution. Objection was taken by the urban council to the compulsory condition imposed by Mrs. Vaughan and some members regarded the site as unsuitable and inconvenient. Dr. John Jones strongly urged his fellow councillors to accept the offer; if not they undertook a great responsibility and made a retrograde step. The hospital would be entirely under the council's control and the new condition would be an advantage. On a vote a motion was carried, inasmuch as the rural district council declined to coöperate and as there was no power to spend money outside the district, not to take any further action. Four members only voted for an amendment to accept Mrs. Vaughan's offer with the new condition. Another amendment that it was essential to erect the hospital without any restrictions was not accepted and there the matter was left.

Enteric Fever at Basingstoke.

As the result of the recent epidemic of enteric fever at Basingstoke, the cause of which was traced to the town water-supply, the borough council had 50 actions for damages entered against it in the High Court, the damages claimed aggregating nearly £4000. By arrangement a committee of the claimants met a committee of the Ratepayers' Association, with the result that the council has agreed to pay £1671 in settlement of the actions without prejudice and with denial of liability.

Sept. 24th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Edinburgh Post-Graduate Course.

THIS course was opened on Sept. 17th by a meetin in the anatomical theatre of the University, presid over by Principal Sir William Turner. The chairm welcomed those who had come to avail themselves post-graduate instruction and expressed his confidence th all those who had undertaken the giving of instructio would do so most conscientiously. Dr. Byrom Bramwe then addressed the meeting, dwelling upon the need the was for such a course in Edinburgh to enable graduates brush themselves up and to acquaint themselves with th newer methods of clinical investigation. Clinical investig tion had become much more elaborate than it used to b and in the Edinburgh school where much attention w given to teaching all these methods were in use. Imme diately after this introductory meeting the work the programme was entered upon. There has bee an unexpectedly large number of graduates come forwa for this course, but so far as can be gathered the are much pleased at the provision which has been mad for them. Some of the more technical classes hav been a little hampered by the numbers entering f them, but this has been arranged as well as possible an in future years provision can be made for larger number Amongst the entertainments provided are a reception give by the Royal College of Physicians of Edinburgh and at-home by the President of the Obstetrical Society. Th course lasts for three weeks and the days are filled fro 9 A.M. to 4 or 5 P.M.

Eyesight of Glasgow Children.

A report on the eyesight of the children attending t Glasgow schools has just been handed in by Dr. H Wrig Thomson to the school board of Glasgow. There is nothi particularly new in the report, but it should be useful calling attention afresh to the undoubted evils which handic our educational system and to some of the obvious remedie The teachers tested the visual acuteness of 52,493 childr and found 18,565, or 35 per cent., to be below what regarded as the normal standard. Dr. Thomson examin the 18,565 defectives by retinoscopy and found tha 11,209, or 21 per cent. of the whole, had ocular defects. The percentage with ocular defects was fairly constant in all the schools, but the percentage with defective vision was very variable—i e., many children with normal eyes were found to see badly. The proportion of these cases was highest in the poor and closely built districts and in old schools, and was lowest in the better class schools and in those near the outskirts of the city. The proportion of such cases in the country schools of Chryston and Cumbernauld was much lower than in any of the city schools; and in industrial schools, where the children are fed at school, the proportion was lower than among board school children of a corresponding social class. Defective vision, apart from ocular defect, seems to be due partly to want of training of the eyes for distant objects and partly to exhaustion of the eyes, which is easily induced when work is carried on in bad light or the nutrition of the children is defective from bad feeding and unhealthy surroundings. Regarding training of the eyes for distant objects, Dr. Thomson thinks that much might be done in the infant department by the total abolition of sewing, which is definitely hurtful to such young eyes, and

EGYPT.

(FROM OUR OWN CORRESPONDENT.)

Wellcome Research Laboratories.

THE second report of these laboratories, which are attached to the Gordon Memorial College at Khartoum, has now been issued and, thanks to the munificence of Mr H. S Wellcome, the report is not only three times the size of the former one but is illustrated by 21 beautiful plates, mostly coloured. and by more than 100 illustrations. The greatest credit is due to the editor and director of the laboratories, Dr. Andrew Balfour, who, less than three years ago, started work at Khartoum with one laboratory boy and two black servants. He is now aided by a chemist, a travelling naturalist, an economic entomologist, and two European assistants. The first photograph shows very strikingly a dust storm sweeping over Khartoum in the month of June and illustrates one of the difficulties encountered in a town where there are no double windows, electric fans, electric light, or dust-proof rooms. There is every indication that much good work will continue to be done in these laboratories, for two Carnegie Research Fellows have been invited to conduct investigations there, the one working on chemical and the other on bacteriological or pathological lines, and a floating laboratory for collecting museum specimens from the various rivers will soon be organised The anti-mosquito work has been well continued, for although it was originally noted that more than half of the wells and pools were infected, anophelines and malaria are practically banished, the stegomyia is seldom found, the dangerous pyretophorus is kept in abeyance, and the ubiquitous culex has ceased to be a nuisance. It has been found that the amount of oil which must be used per well need never exceed half a pint and that even two ounces have been found to be ample if none of the oil is lost by splashing. Only six men are engaged in this work under an English inspector, so that for less than £100 per annum Khartoum is kept practically free from malaria and from the perpetual torment of mosquitoes. Dr. Balfour states that 16 different genera, comprising some 35 species of culicidæ, have now been found in the Soudan. There is a special article on biting and noxious insects other than mosquitoes, including tsetse fly, the jigger, ticks, and locusts. The glossina morsitans, the carrier of trypanosomiasis in animals, has been found as far north as latitude 12° N., and is very numerous in the Bahr-el-Ghazal province, where it causes great loss amongst mules and donkeys. The glossina palpalis has been discovered north of latitude 5°, close to the Lado Enclave, and stringent orders have been given to prevent any recruiting into the Egyptian army from the natives of Uganda and other districts already invaded by sleeping sickness. Mr. Austen and Mr. Theobald, of the British Museum, have written valuable descriptions, beautifully illustrated, of *blood-sucking and other diptera and* mosquitoes from the Soudan. Though sleeping sickness has so far not been encountered within the Soudan, it is to be remembered that Dr. Todd mentions the occurrence of a case at the Lado Enclave, and that Dr. Neave found Leishman-Donovan bodies in the spleen of a boy coming from the Bahr-el Ghazal. A detailed account is given of inoculation experiments on dogs, monkeys, and mice with the trypanosome of mules. Chrysoidin has been tried on patients suffering from various tropical diseases, including a boy from Uganda, who has trypanosomes in his blood. No definite cure has been obtained but Dr. Balfour reports that this dye seems to cause a disappearance of the trypanosomes from the peripheral blood and from the gland juice; the only disadvantage of the treatment is that the drug is distinctly irritating to the kidneys, causing copious albuminuria, and must therefore be used with caution. Dr. Neave made some experiments to test the therapeutic effect of the blood serum of wild animals (water buck) from trypanosome-infected districts on animals inoculated with trypanosomiasis. Rabies has occurred in Khartoum and there has been one case of hydrophobia; several fatal cases of diphtheria took place during the year among native babies; enteric fever is still rare; bacillary dysentery is not uncommon amongst the Egyptian soldiery; and one rare case of hydatid of the femur causing extensive erosion of the bone was sent by Captain S. L. Cummins, R A M.C Dr. Neave gives an excellent account of the various parasites which he met with in the southern part of the Soudan and Dr. Bean furnishes a report of the chemical section of the laboratories. He examined 42 samples of river water and 15 of well waters, besides making 150 other analyses. He finds that the White Nile is never free from an appreciable amount of suspended matter, while the Blue Nile, on the contrary, although carrying in flood an enormous amount of mud, becomes almost clear from January till June. The highest proportion found was on August 12th, 1166 parts per 1,000,000. and the lowest on Jan. 12th, only 4 parts per 1,000 000. A dairy, under Government management, exists in Khartoum, but it is only open during the five cool months; for the rest of the year no butter is to be had and the only milk available is that supplied by natives from goats and cows. The Europeans are therefore driven to use milk powders, which are prepared by evaporating milk to dryness on a revolving cylinder, and by heating to 230° F. Dr. Bean praises this milk for those travelling in the interior. It is bacteriologically sterile, and the powder, if made into a preliminary paste, can be mixed with hot water and the reconstituted milk proves to be of very agreeable taste. He even suggests that milk powder would be extremely useful for those unable to digest ordinary milk. It appears that the chief gum-producing countries are the Anglo-Egyptian Soudan and the French colony of Senegal, and that the production of gum, as shown by Greig Smith, is due to a specific microbe, named bacterium acaciæ, the gum being formed from the wandering sugars, levulose and maltose, in the sap. A native remedy for syphilis in the Soudan is an earth dissolved in water, and called tureba; Dr. Bean finds it contains no mercury, as reputed, but that it is merely a saline purgative. Enough has been said to show that this report is well worth reading.

Sept. 18th.

AUSTRALIA.

(FROM OUR OWN CORRESPONDENT.)

Bubonic Plague.

A WHARF labourer suffering from plague was removed to the Coast Hospital, Sydney, on July 23rd. A previous fatal case was supposed to have been contracted at the wharves, the patient having been a shipping clerk. A plague-infected area has, however, been discovered at Exmore in the vicinity of the house in which he had lived. No further cases of plague have developed among the passengers of the Peninsular and Oriental steamer *Britannia* which was quarantined at Adelaide.

Scarlet Fever.

An epidemic of scarlet fever has broken out at Sydney and its suburbs The number of cases notified for the fortnight ending August 11th was 223. The mortality is about from 1 to 1½ per cent. Inquiries made by the health department showed that the spread of the disease was due solely to infection in the ordinary way and that the milk-supply had nothing to do with it.

Hospital Affairs.

This is the time of year when nearly all the hospitals and charitable institutions hold their annual meetings and elect their governing bodies.—The meeting of the supporters of the Melbourne Hospital was held on July 25th. The report stated that the income of the institution has, for the second year in succession, been sufficient to meet the expenditure without recourse to extraordinary appeals. The ordinary income for last year was £23 671 which, with extraordinary income amounting to £4827, brought the total income for the year up to £28 498. The total expenditure for last year was £25 224. During the year 23 388 patients were treated at the hospital. Of these 4802 were in-patients, 11,328 were out-patients, and 7258 were casualty cases. With reference to the provision made in Victoria for the treatment of consumptives the committee expressed the view that it is improper that a large number of persons in various parts of the State who contract the disease should, when it had reached a hopeless stage, be sent to a city hospital for treatment The total provision made for consumption in the State was altogether inadequate. It is estimated that in Victoria 2000 persons die annually from the effects of tuberculosis.—A steady year's work was reported at the annual meeting of contributors to the Queen Victoria Memorial Hospital for Women and Children, Melbourne Treatment had been given to 263 in-patients and 2909 out-patients. Of the in-patients constitution will be framed by a special edict. According to the Order in question the numbers of the officers will be as follows for each grade respectively: *Médecins principaux* of the first class, 12; *médecins principaux* of the second class, 18; *médecins-majors* of the first class, 88; *médecins-majors* of the second class, 175; *médecins aide majors* of the first and second classes, 141; *pharmaciens principaux* of the first class, 1; *pharmaciens principaux* of the second class, 2; *pharmaciens-majors* of the first class, 5; *pharmaciens-majors* of the second class, 19; and *aide-majors* of the first and second classes, 19.

Bani Sickness.

At a meeting of the Academy of Sciences held on Sept. 17th M. Laveran communicated a note from M. Cazalbou, military veterinary surgeon, upon the diffusion of a trypanosomiasis brought about by a fly other than the glossina. This fly is closely related to the tsetse. M. Cazalbou having discovered that a focus of trypanosomiasis existed in the Bani district, the Bani being an affluent of the Niger, captured some of the flies in question and brought them down to Segou where some dogs which had been proved to be free from trypanosomiasis were bitten by them. Two out of seven dogs were infected.

The Association for the Repression of the White Slave Traffic

The Third International Congress for the Repression of the White Slave Traffic will be held in Paris from Oct. 22nd to 25th. The following can take part in the Congress: (1) Official delegates of Governments and public bodies; (2) delegates from associations and committees organised in the respective countries for the repression of the traffic; and (3) representatives of philanthropic associations and various persons interested in the study of social questions. Every national committee can send ten delegates. Every member of the Congress without exception must contribute a subscription of 20 francs and in return for this will have a right to all publications, papers, and transactions of the sittings of the Congress. All papers to be read before the Congress should be edited and translated into French at the expense of the national committees. The deliberations of the Congress will be held in the French language. Foreign members, however, can speak in their own language if they like but a *résumé* of their subjects must be communicated in French to the Congress. No speech or paper is to exceed 15 minutes in delivery. The transactions of the meetings will be eventually issued and sent to every member of the Congress. Subscriptions should be sent to M. Loys Brueyere, treasurer of the French Association, 10, Rue Pasquier, Paris.

Sept. 25th.

ROME.

(FROM OUR OWN CORRESPONDENT.)

The Fourth Congress of the National Association of Medici Condotti at Milan.

A CONGRESS of 6000 members! This was the muster of *medici condotti* at Milan on August 30th and succeeding two days, assembled to discuss and to protest against the grievances of their long-suffering and much neglected class. The first congress of the association, also held at Milan, numbered barely 300 members. This rapid and enormous growth speaks eloquently of the urgent need there is for reforms and of the determination of the whole service to obtain them. But, as the retiring president, Dr. Villa, remarked, the task is no easy one owing to the inertia of the governing powers and the frequent changes of ministry, by reason of which constantly renewed efforts on the part of the service are rendered necessary in order to accomplish anything. In proof of this ineptitude of the Government he pointed to the unwarrantable delay in the publication of the regulations affecting the sanitary law of February, 1904, and to their failure to grant study leave and to provide gratuitous courses at the universities whereby the *medico condotto*, whose lot was so often cast in remote isolated country districts, might at intervals be enabled to refresh his knowledge and thus be the better prepared to wrestle with the socio sanitary problems which so profoundly affect the welfare of the poorer classes—such, for instance, as the propagation of syphilis, the excessive infant mortality, the ravages of tuberculosis and alcoholism, and the havoc wrought by malaria. These remarks of Dr. Villa had their sequel in a telegram from the Minister of the Interior which was read at the following sitting assuring the congress of the immediate publication of the regulations; and, indeed, before the conclusion of the congress this publication actually took place. But in announcing the fact the President, Dr. Brunelli, commented adversely on their unsatisfactory nature and after registering a formal protest the congress resolved that at the approaching dissolution of the present Parliament an electoral committee should be formed to secure the election of deputies to the new Parliament favourable to the desired reforms and pledged to vote for them. Amongst other business transacted was the passing of resolutions recommending the popularising of sanitary knowledge by means of conferences to be held by the *medici condotti*; the formation of a committee to study various socio-sanitary problems by means of a series of questions addressed to members; and the giving of a preference to the *medici condotti* in the vicinity, when, under the new *régime* of State control of railways, medical officers should come to be appointed to the different sections along the various lines. A motion was proposed urging the assumption by the State itself of the organisation of the public health service by which means the dependence of the *medici condotti* upon various local bodies subject to pernicious influences might be avoided and their position and freedom of action thus become more assured. This proposition was referred for discussion to the sections and will be brought up again at the next congress. In the form of an order of the day a remonstrance was addressed to the Government for not carrying out more strictly the provisions of the law regulating the practice of medicine and surgery by foreign medical men and of dentistry by dentists not holding a diploma in medicine and surgery. As a mark of their appreciation of Dr. Villa's services as president the members of the congress before separating subscribed a considerable sum to be devoted, under the name of the "Enrico Villa Foundation," to the support of one child at the Perugia College for the orphans of *medici condotti*. Venice was chosen as the seat of the next (the fifth) congress of the association.

Trachoma and Italian Emigrants.

It is a fact, only too well known to the shipping companies engaged in the transport of emigrants from Italy to America, that trachoma is extremely prevalent in this country, so much so that one of the most important qualifications required by a surgeon of an emigrant vessel so engaged is ability in "spotting" this disease. It is not unusual for the ship surgeon who has a little time at his disposal at one of the Italian ports such as Genoa or Naples to employ it in gaining experience at one of the local eye clinics in the diagnosis of trachoma which in its slighter degrees may easily be overlooked by an unwary or unpractised eye, especially when, as is sometimes done "with intent to deceive," the reddened conjunctiva has been temporarily blanched by the application of a solution of cocaine or adrenalin. The United States authorities in particular are extremely strict in regard to it and rigorously exclude its victims from their shores. Any emigrants, therefore, afflicted with it who escape the vigilance of the ship surgeon on embarkation and are inadvertently allowed to cross the Atlantic are not permitted to land at American ports and have to be brought back to Italy at the steamship companies' expense. Its ravages are greatest in Southern Italy but few parts of the kingdom are exempt from the scourge. At Barletta it has become so prevalent that measures have lately been taken by the prefect and syndic to arrest its spread and special arrangements made for the reception and treatment of the patients at the eye hospital.

Pellagra at Fermo.

The extension of pellagra in the province of Fermo has attained such proportions as to determine the provincial council for pellagra to offer prizes for the best method of combating it successfully. Public money has been voted for holding conferences and printing pamphlets on the cultivation of maize, for exchanging sound for deteriorated grain, for the purchase of portable desiccators, and to provide a bonus for those who substitute other crops for maize, who construct suitable granaries for its storage, or who adopt a rational type of hygienic dwelling for their labourers.

Sept. 16th.

253 had been discharged and 27 died. The total expenditure was £1908 and as the actual income was only £1675 a shortage remained of £233 which reduced the credit balance of the institution from £262 to £29.—The annual meeting of the subscribers to the Women's Hospital, Melbourne, was more largely attended than usual owing to a proposal submitted to alter the constitution of the committee. At present it is composed of 15 ladies and six gentlemen, and it was proposed that the 21 members should be elected without distinction as to sex. The reason for the proposed change was that the gentlemen on the committee differed from the ladies about getting competitive designs for new buildings. The ladies want an open competition and the gentlemen consider that the architect who has already done work for the committee should be employed to draw up plans. At the meeting the mover of the proposed alteration found that the feeling of those present was so opposed to him that he withdrew the motion. The annual report stated that the ordinary receipts were £6275, or an increase of £160 over the previous year.

The Medical Practitioners Bill.

The Medical Practitioners Bill has been read a second time in the Legislative Assembly of Victoria. It is practically the same as the Bill submitted last session, providing for a five years' course, giving power to strike names off the Register, and requiring that registration should be given only to graduates of those countries which reciprocated by registering holders of Australian medical degrees. The authorities of the Homœopathic Hospital have taken strong exception to this clause and the five years' course, which would shut out the holders of American degrees, and this is for them a decided grievance, because "America was the only place the hospital could draw on for homœopathic practitioners." A somewhat similar Bill, providing for reciprocity, has been read a first time in the Legislative Assembly of New South Wales.

Obituary.

Dr. Alexander Barber died at Paddington, Sydney, on August 13th, at the age of 54 years. He had practised at Penrith over 12 years ago and was noted for his many acts of charity and the interest he took in the affairs of the district. The attendance at his funeral was the largest seen in the district for many years. He was a Government medical officer and a member of the licensing bench. He suffered from an internal tumour, for which an operation was performed but without affording relief.

August 18th.

Obituary.

DAVID HENRY GOODSALL, F.R.C.S. ENG.,

SENIOR SURGEON TO THE METROPOLITAN HOSPITAL, ETC.

THE sudden death of Mr. D. H. Goodsall has come as a great shock to his many friends. He had recently returned from his holiday, looking better than he had done for some months. On the morning of Sept. 12th he had what, judging from subsequent events, may be called a slight anginal attack. He paid little attention to it and worked in his usual strenuous manner on that day and the next. On Friday, Sept. 14th, while in the City, he had a recurrence of the pain and when he reached home he was pulseless and in great agony. Under treatment the pain ceased and he appeared to be settling down quietly when he had an attack of heart failure and the end came shortly before midnight.

Mr. Goodsall was born on Jan. 4th, 1843, the second of four brothers. His father, who was a student at St. Bartholomew's Hospital, was pricked in the hand while engaged in making a post-mortem examination in the hospital, death being the result. He left a widow and four sons entirely unprovided for.

Mr. D. H. Goodsall was taken early from school and apprenticed to a druggist near Aldgate at about the age of 14 years. From this age he kept himself entirely. He entered St. Bartholomew's Hospital in October, 1865, being excused his fees on account of his father's death. While at the hospital he kept himself by acting as dispenser and assistant to a medical practitioner in Finsbury-square. In 1868 he was admitted a Member of the Royal College of Surgeons of England and a Licentiate of the Royal College of Physicians of London in 1870. After holding the post of midwifery assistant at St. Bartholomew's he was appointed house surgeon at St. Mark's Hospital in 1870. In 1871 he became assistant surgeon to the hospital and about this time he took up his residence in Finsbury-square and assisted the late Mr. Gowlland in his practice. It was doubtless his early connexion with St. Mark's and the opportunity he had of seeing Mr. Gowlland's extensive rectal practice which led Mr. Goodsall to take up the branch of surgery in which he so greatly excelled. In 1872 Mr. Goodsall was admitted a Fellow of the Royal College of Surgeons and in the same year he was appointed surgeon to the Metropolitan Hospital, becoming senior surgeon in 1892, which office he held at the time of his death. At St. Mark's he became surgeon in 1888 and eventually senior surgeon, and owing to age limit, he retired in 1903. He was also surgeon to St. Saviour's Hospital. But the work done by Mr. Goodsall in the out-patient departments and wards of the hospitals with which he was connected was only a part of his labours on behalf of these institutions. The following extract from a letter from the secretary of the Metropolitan Hospital will give some idea of the amount of time which Mr. Goodsall devoted to the hospital: "He was associated with the hospital when it was in Devonshire-square, City, then in the temporary premises in Commercial-street, and was largely instrumental in securing our present site. During the past 18 months he has been endeavouring to get a site for a nurses' home. Though he was the busiest man I think I have ever met he was always a most regular attendant at all meetings of committees and was a member of each of the seven regular committees. With the single exception of the late chairman (Mr. Joseph Fry, who founded the hospital in 1836 and who for 60 years practically obtained all its income) no man has done so much for the hospital as Mr Goodsall. His death to the 'Metropolitan' is overwhelming."

Mr. Goodsall was a Fellow of the Statistical Society, of the Royal Medical and Chirurgical Society, of the Medical Society of London, and of the Hunterian Society, and a member of the Clinical Society. He was joint author (with Mr. W. E. Miles) of "Diseases of the Anus and Rectum," and he contributed valuable papers on the same subject to St. Bartholomew's Hospital Reports and various periodicals. His writings were like the man—concise and to the point. He was a most careful and painstaking surgeon who left nothing to chance, and if he thought his patient was in imminent danger he would stay up all night and look after him. It is not to be wondered, therefore, that he obtained most excellent results in the special branch of surgery to which he had devoted his energies.

But Mr. Goodsall was something more than a surgeon: he was gifted with great business capacity and found time to be on the directorate of the Odessa Waterworks Company and at the time of his death he was one of the directors of the Western Telegraph Company and managing director of a printing company. Even these multifarious duties did not exhaust his energies, as the work he did for the Medical Society will prove. For 19 years he was chairman of the house and finance committee and honorary treasurer since 1896. In his hands these posts were no sinecures, so that his loss will be severely felt by the Medical Society, especially as in the last 12 months he has been taking the leading part on behalf of the society in the negotiations which have been going on for the union of the London medical societies. Only the most robust health could have stood the strain of such excessive work, and for 50 years Mr. Goodsall had not spent a day in bed for illness. He had little time for the ordinary social enjoyments but he dearly loved a game at chess or watching a good contest.

No one will be more missed by his friends, as he was ever ready to give his advice and assistance and always seemed to find time to help his friends out of their difficulties. He leaves a widow and one son. In accordance with his wish his body was cremated at the Golder's Green Crematorium on Sept. 18th.

GIFT TO KILMARNOCK NURSING ASSOCIATION.—The Kilmarnock Nursing Association has received from the estate of the late Mrs. Hannah Finnie, of the Abbey, Malvern Wells, the sum of £1000, which has been allocated to the institution by the trustees of the deceased. Recently a gift of £2000 came to the local infirmary from the same source.

HAMPSTEAD GENERAL HOSPITAL.—Resident Medical Officer for six months. Salary £80 per annum, with board and residence.

HULL ROYAL INFIRMARY.—Honorary Physician.

LEEDS PUBLIC DISPENSARY.—Honorary Medical Officer.

LEICESTER INFIRMARY.—Resident Surgical Dresser for six months. Honorarium £10 10s., with board, lodging, and washing.

LIVERPOOL, CITY OF.—Assistant Medical Officer of Health. Salary £250 per annum.

LIVERPOOL INFECTIOUS DISEASES HOSPITAL.—Assistant Resident Medical Officer, unmarried. Salary £120 per annum, with board, washing, and lodging.

MACCLESFIELD, CHESHIRE COUNTY ASYLUM.—Junior Assistant Medical Officer, unmarried. Salary £140, rising to £160, with apartments, board, and washing.

MACCLESFIELD GENERAL INFIRMARY.—Junior House Surgeon. Salary £60 per annum, with board and residence.

MANCHESTER, CHORLTON UNION WORKHOUSE HOSPITALS, Withington.—Senior and Junior Resident Medical Officers. Salary £100 per annum, with rations, apartments, and attendance.

MANCHESTER ROYAL INFIRMARY AND DISPENSARY.—Honorary Assistant Physician.

METROPOLITAN HOSPITAL, Kingsland-road, N.E.—Surgeon. Also Assistant Surgeon.

PADDINGTON GREEN CHILDREN'S HOSPITAL, London, W.—House Physician and House Surgeon, for six months. Salary at rate of 50 guineas a year, with board and residence.

PADDINGTON INFIRMARY.—First Assistant to the Medical Superintendent and Assistant Medical Officer, unmarried. Salary £100 per annum, rising to £120, together with board, lodging, and washing. Also Second Assistant to the Medical Superintendent for six months. Honorarium of £36 and board, lodging, and washing.

PORTSMOUTH, ROYAL PORTSMOUTH HOSPITAL.—House Surgeon. Salary £100 per annum, with board, residence, and laundry.

ROYAL FREE HOSPITAL, Gray's Inn-road, W.C.—House Physician and Casualty House Surgeon for six months. Board, &c., are provided. Also Resident House Physician and Resident House Surgeon. Board, &c., are provided.

SAMARITAN FREE HOSPITAL FOR WOMEN, Marylebone-road, N.W.—Clinical Assistants.

ST. MARY'S HOSPITAL FOR WOMEN AND CHILDREN, Plaistow, E.—Assistant Resident Medical Officer, unmarried. Salary at rate of £80 per annum, with board, residence, and laundry.

SEAMEN'S HOSPITAL SOCIETY, Greenwich, S.E.—*DREADNOUGHT HOSPITAL*, Greenwich:—Two House Physicians and Two House Surgeons for six months. Salaries at rate of £50 per annum, with board, residence, and washing. Also Honorary Dental Surgeon. Also Honorary Medical Officer *for the Electrical Department*. BRANCH HOSPITAL, Royal Albert Dock, E.:—Senior House Surgeon for six months. Salary at rate of £75 per annum and additional £25 per annum for acting as Registrar, &c., with board, residence, and washing. Also House Surgeon *for six months*. Salary at rate of £50 per annum, with board, residence, and washing. Also Honorary Anæsthetists.

SHEFFIELD, CITY OF.—Visiting Medical Officer for Schools. Salary £400 per annum.

SOUTH LAMBETH, STOCKWELL, AND NORTH BRIXTON DISPENSARY, Wilkinson-street, Albert-square, Clapham-road.—Vacancy in the Medical Staff.

STAFFORDSHIRE COUNTY ASYLUM, Cheddleton, Leek.—Assistant Medical Officer, unmarried. Salary £150, rising to £200, with furnished quarters, board, and washing.

WOLVERHAMPTON AND STAFFORDSHIRE GENERAL HOSPITAL.—House Physician. Salary £100 per annum, with board, lodging, and laundry. *Also House Surgeon*. Salary £100 per annum, with board, lodging, and laundry.

THE Chief Inspector of Factories, Home Office, S.W., gives notice of a vacancy as *Certifying* Surgeon under the Factory and Workshop Act at Fulham and Hammersmith, in the county of London.

Births, Marriages, and Deaths.

BIRTHS.

METCALFE.—On Sept. 24th, at 2, St. Leonards, York, the wife of A. W. Metcalfe, M.A., M.D., of a daughter.

NASH.—On Sept. 20th, at Oulton House, Accrington, the wife of Elwin H. T. Nash, M.R.C.S., L.R.C.P., of a son.

NEWTON.—On Sept. 21st, at Brook-hill, Sheffield, the wife of Duncan Gray Newton, F.R.C.S., of a son.

STURROCK.—On Sept. 23rd, at Arima, Broughty Ferry, the wife of J. F. Sturrock, M.B., L.R.C.S. Edin., of a son.

SUTTON.—On Sept. 21st, at Clare House, Sidcup, the wife of C. R. Arnold Sutton, M.A., M.D. Camb., of a son.

WILLIAMSON.—On Sept. 21st, at Trelawney, Springfield-road, Leicester, the wife of Lieutenant-Colonel J. G. Williamson, R.A.M.C. (retired), of a daughter.

MARRIAGE.

BUCKLEY—LANYON.—On Sept. 20th, at St. Peter's, Croydon, James Charles Buckley, M.D., of Nottingham, to Mabel, youngest daughter of the late John Charles Lanyon and of Mrs. Lanyon, of South Croydon.

DEATHS.

BIRT.—On Sept. 19th, at Reading, Thomas Birt, Major, R.A.M.C., aged 41 years.

MACDONALD.—On Sept. 25th, at Carden-place, Aberdeen, James Macdonald, M.D., F.R.C.S. Eng., late H.M.I.S., in his 79th year.

TWEEDY.—On Sept. 21st, at Rutland-square, Dublin, Henry Tweedy, M.D., in his [illegible]th year.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

A DEPARTURE IN AGENCY ROUTINE.

A MEDICAL correspondent who is the licensee of a home for inebriates has forwarded to us some papers which he has received from the Southern Medical and Scholastic Agency, Limited. The secretary of this company informs our correspondent that they "are about to issue and advertise widely a list of those willing *to receive resident patients* and if you wish an advertisement of your requirements inserted kindly fill in and return the enclosed form." The fee for an advertisement in the forthcoming list is 10*s*. 6*d*. per annum which cannot be called expensive, but in "the enclosed form" we find the following guarantee has to be signed:—

> "I herewith enclose the fee agreed (10*s*. 6*d*.) for registration and advertisement referred to and I further undertake to pay to you 5 per cent. upon all fees received from any patient introduced by you during the first six months of their residence at my house."

The departure of the Southern Medical and Scholastic Agency is open to criticism.

THE CONSULTANT AND THE GENERAL PRACTITIONER.

To the Editors of THE LANCET.

SIRS,—I was interested in the letter signed "M.B. Lond." in THE LANCET of Sept. 22nd, p. 841. Personally, I have received the very greatest kindness, courtesy, and help from consultants in every part of England except once, some 20 years since, when a patient, and personal friend, took his daughter, without my knowledge, to a consultant at Liverpool. On his returning home he called to *see me* at once and told me that the consultant seemed annoyed that there was no letter from me and asked me to write to him; this I did, giving a full account of the family history, which was *not* favourable. The consultant sent the letter direct to my patient; needless to say I lost both friend and patient.

I am, Sirs, yours faithfully,

Millom, Cumberland, Sept. 22nd, 1906. PERCY B. STONEY.

To the Editors of THE LANCET.

SIRS,—I have had some strange experiences with consultants. I have had dealings with one who generally fixes the *time* so that the medical man in charge only gets the message some time after the hour fixed, the consultant examines the patient alone and tells the patient that he will write to tell his medical man, say what is wrong and what he *recommends* should be done. I give some facts regarding the last case saw with this consultant. A club patient suffering from intestinal obstruction was doing well at 7.45 one Friday evening, when called, and there was no mention of a consultation. At 9.30 the same night a messenger brought word that a consultant would be at the patient's house (a mile away) at 10 P.M. I met him. On Saturday I was asked to meet him again and did so. On calling on Sunday night I was *told* that the consultant had called to inquire how the patient was (I think he saw the patient) and had offered to meet me again on Monday if I wished it, and I, perhaps foolishly, met him again. On the Tuesday I got a note *from* the patient's wife telling me that the consultant had taken the case over and I need not call again. The consultant kept that case on for two or three months without a word or note to me.

This case raises other points. The patient was an Oddfellows' secretary and was paying 4*s*. per annum. (*a*) What should the club medical officer charge for the three consultations practically forced upon him at inconvenient times? (*b*) The patient has been ill again and asked him to call. What should he do? I am a lover of peace and wish to do right.

I am, Sirs, yours faithfully,

Sept. 24th. M.B. Edin.

⁂ (*a*) The club medical officer must be bound by the rules of the society, in whose service he is, as regards the fees for consultations, if such rules exist. If there are no such rules we think he should charge his usual consultation fees. (*b*) He may well *refuse* to see the patient again but as he describes himself as a lover of peace he may prefer to continue attendance.—ED. L.

ANCIENT OCULISTS.

AN interesting instance of the comradeship of men of science notwithstanding political international rivalries was recently provided by the eulogium passed at the French Academy upon Dr. J. *Hirschberg*, *professor of ophthalmology* at the University of Berlin. He, not content with his onerous professorial duties and the calls of a large practice, has devoted many years to the formation of a medical library which in 1901 had become so extensive that the catalogue comprised 431 pages. But he has also been making a complete study of the work of ancient oculists and as a result has published the following works. His first book on the historical branch of the subject appeared in 1890 and was entitled "Egypt: Historical Studies of an Oculist." The second was the publication, in 1899, of the "Oculistica" of Aetius of Amida, which he gives in the original Greek and also in a Latin translation. This was followed in the same year by a "History of the Oculists of Antiquity," which treats of the therapeutics of the that such child shall forthwith be separated from the children in health. The Board trusts that the guardians will give the matter their careful consideration and will take such action as is requisite with a view to secure that all children of the classes specified who come under their care may be as promptly as possible removed to such institutions of the managers as are suited to their respective requirements.

THE TORQUAY EDUCATION COMMITTEE AND CHILDREN WITH DEFECTIVE EYESIGHT.—At a meeting of the Torquay education committee held on Sept. 18th, Dr. H. V. Mackenzie was appointed to examine children with defective eyesight at a honorarium of £50 per annum. There was some opposition to the appointment, which will have to be confirmed by the town council, and a letter was read from the Local Government Board stating that, although in any case where there was reasonable suspicion that a child was suffering from an affection of the eyes of a contagious character the local education authority might call in a medical practitioner to examine the child and pay him a reasonable fee for so doing, the authority was not authorised to incur expenditure in the employment of a medical man to examine school children with a view to remedies being prescribed in cases where the eyesight was defective.

THE DELAMERE SANATORIUM.—A scheme has been prepared and is now under the consideration of the Charity Commissioners for the future administration of the Crossley Sanatorium at Delamere and the Manchester Hospital for Consumption and Diseases of the Throat and Chest, consisting of an out-patient department in Manchester and an in-patient hospital at Bowdon. They are to be consolidated and managed as one institution under the title of the Manchester Hospital for Consumption and Diseases of the Throat and Chest. There is to be a body of 16 trustees entitled to hold office for life, in whom all property is to be vested. The institution is to be maintained, extended, and supported by means of bequests, annual subscriptions, or other gifts, the contributions and payments of patients, the income derived from the invested funds, and in case of need the capital may be used under certain conditions. The governors are to have the power of nominating new trustees. The personal estate of the institutions amounts to about £80,000.

BOOKS, ETC., RECEIVED.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.*

BURFIELD, J., M.B., B.S. Lond., F.R.C.S., Eng., has been appointed Assistant Medical Officer at the Bolingbroke Hospital, Wandsworth Common, S.W.

CASHMAN, JAMES P., M.B., B.S. R.U.I., has been appointed Resident Medical Superintendent of the Cork District Asylum.

DAWNAY, A. H. PAYAN, M.R.C.S., L.R.C.P. Lond., has been appointed Honorary Ophthalmic Surgeon to the Hounslow Hospital.

DEANE, JOHN EDWARD JAMES, L.K.Q.C.P., L.F.P.S. Glasg., has been appointed Officer of Health for Eaglehawk, Victoria, Australia.

HARRIS, JOHN RICHARDS, M.D. Melb., has been appointed Public Vaccinator for the North-Eastern District, Victoria, Australia.

HILL, ARTHUR MACHEN, M.B. Melb., has been appointed Public Vaccinator for the Midland District, Victoria, Australia.

JEPHCOTT, CHARLES, M.B., B.S. Cantab., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer to the Chester Union by the Chester Board of Guardians.

MOSSOP, E. E., M.B., B.S. Lond., M.R.C.S., L.R.C.P. Lond., has been appointed House Physician at the Hospital for Sick Children, Great Ormond-street, W.C.

RENDALL, PERCY, M.D., M.R.C.S., has been appointed Divisional Surgeon to the V Division of Metropolitan Police at Epsom.

SWEET, WILLIAM SYDNEY, M.B., B.S. Lond., has been appointed Officer of Health for the West Riding of Maffra, Victoria, Australia.

TIVY, CECIL B. F., M.B., B.Ch. R.U.I., has been appointed House Surgeon to the Cork Eye, Ear, and Throat Hospital.

Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (9.30 A.M.), Royal Free (2 P.M.), Guy's (1.30 P.M.), Royal Ear (2 P.M.), Children, Gt. Ormond-street (2 P.M.).

TUESDAY (2nd).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (1.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), West London (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (1 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Soho-square (2 P.M.), Chelsea (2 P.M.), Central London Throat and Ear (2 P.M.), Children, Gt. Ormond-street (2 P.M., Ophthalmic, 2.15 P.M.).

WEDNESDAY (3rd).—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing Cross (3 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), King's College (2 P.M.), St. George's (Ophthalmic, 1 P.M.), St. Mary's (2 P.M.), National Orthopædic (10 A.M.), St. Peter's (2 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Gt. Northern Central (2.30 P.M.), Westminster (2 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Cancer (2 P.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Royal Ear (2 P.M.), Royal Orthopædic (3 P.M.), Children, Gt. Ormond-street (9.30 A.M., Dental, 2 P.M.).

THURSDAY (4th).—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), University College (2 P.M.), Charing Cross (3 P.M.), St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex (1.30 P.M.), St. Mary's (2.30 P.M.), Soho-square (2 P.M.), North-West London (2 P.M.), Gt. Northern Central (Gynæcological, 2.30 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Royal Orthopædic (9 A.M.), Royal Ear (2 P.M.), Children, Gt. Ormond-street (2.30 P.M.).

FRIDAY (5th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Charing Cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), St. Mary's (2 P.M.), Ophthalmic (10 A.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), City Orthopædic (2.30 P.M.), Soho-square (2 P.M.), Central London Throat and Ear (2 P.M.), Children, Gt. Ormond-street (9 A.M., Aural, 2 P.M.), St. Mark's (2.30 P.M.).

SATURDAY (6th).—Royal Free (9 A.M.), London (2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), University College (9.15 A.M.), Charing Cross (2 P.M.), St. George's (1 P.M.), St. Mary's (10 P.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Children, Gt. Ormond-street (9.30 A.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

SOCIETIES.

WEDNESDAY (3rd).—OBSTETRICAL SOCIETY OF LONDON (20, Hanover-square, W.).—8 P.M.: Specimens will be shown by Dr. Eden, Dr. R. D. Maxwell, and Dr. H. R. Andrews. Short Communication:—Dr. Eden and Mr. F. L. Provis: A Case of Intra-ligamentous, Fibro-cystic Tumour *of the Uterus, weighing about 30 pounds,* Successfully Removed by Enucleation and Sub-total Hysterectomy. Paper:—Mr. E. E. Young: Primary Tuberculosis of the *Cervix Uteri.*

FRIDAY (5th).—WEST LONDON MEDICO-CHIRURGICAL SOCIETY.—8.30 P.M.: *Presidential Address*:—*Dr.* L. Mark: Art and Medicine.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

MONDAY (1st).—POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—2 P.M.: Medical and Surgical Clinics. 2.30 P.M.: X Rays. Operations. Diseases of the Eye.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M.: *Dr. J. H.* Sequeira: Clinique. (Skin.) 5.15 P.M.: Lecture:—Sir H. D. Littlejohn: The Practice of Forensic Medicine.

TUESDAY (2nd).—POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—2 P.M.: Medical and Surgical Clinics. 2.15 P.M.: Diseases of the Throat, Nose, and Ear. 2.30 P.M.: X Rays. Operations. Diseases of the Skin.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M.: Dr. L. Guthrie: Clinique. (Medical.) 5.15 P.M.: Lecture:—Mr. J. Pardoe: Misleading Symptoms in Urinary Disease.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC (Queen-square, Bloomsbury, W.C.).—3.30 P.M.: Clinical Lecture:—Dr. Collier: Local Lesions of Spinal Cord - Anatomy.

WEDNESDAY (3rd).—POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—10 A.M.: Diseases of the Throat, Nose, and Ear. Diseases of Children. 2 P.M.: Medical and Surgical Clinics. 2.30 P.M.: X Rays. Operations.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M.: Mr. T. P. Legg: Clinique. (Surgical.) 5.15 P.M.: Lecture:—*Dr. G. H. Savage: Lucid Intervals in Cases of Insanity.*

THURSDAY (4th).—POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—2 P.M.: Medical and Surgical Clinics. 2.30 P.M.: X Rays. Operations. Diseases of the Eye.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M.: Mr. Hutchinson: Clinique. (Surgical.) 5.15 P.M.: Lecture:—Dr. G. F. Still: Head-nodding and other Curious Movements in Children.

CHARING CROSS HOSPITAL.—4 P.M.: Dr. Murray: Demonstration (Medical). (Post Graduate Course.)

FRIDAY (5th).—POST-GRADUATE COLLEGE (West London Hospital, [illegible] ical Clinics. 2.15 P.M.: Diseases of the Throat, Nose, and Ear. 2.30 P.M.: X Rays. Operations. Diseases of the Skin.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M.: Dr. D. Grant: Clinique. (Ear.)

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC (Queen-square, Bloomsbury, W.C.).—3.30 P.M.: Clinical Lecture:—Dr. Collier: Local Diseases of Spinal Cord - Diagnosis.

SATURDAY (6th).—POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—10 A.M.: Diseases of the Throat, Nose and Ear. 2 P.M.: Medical and Surgical Clinics. 2.30 P.M.: X Rays. Operations.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the *subscription is* paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularity in the despatch of their Journals and an earlier delivery than the *majority* of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 12 6	*One Year*	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	*0 8 8*

Subscriptions (which may commence at any time) are payable in advance. *Cheques* and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be *made* payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the *terms* of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and Agents are authorised to collect, and generally do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased *to* forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied. Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND.

diseased eye among the Egyptians, Hindoos, Greeks, Romans, and Byzantines. In 1902 he published, with the assistance of Herr M. J. Lippert, a most competent Arabic scholar, the Oculistics of Avicenna; more recently a study of all the known works of Arabic oculists; and finally, in 1905, a "History of Arabic Oculist Science." It is to be hoped that now that the committee of the Berlin Corpus of Latin Inscriptions has published the volume containing the oculist seals Dr. Hirschberg will write a medical and pharmaceutical commentary upon these texts, for the comprehension of which his erudition renders him *pre-eminently qualified*.

DENTISTS' CHARGES TO MEDICAL MEN.

To the Editors of THE LANCET.

SIRS,—May I ask your own and others' opinions anent what follows? I had a set of artificial teeth inserted lately by the son of a brother practitioner, an L.D.S., *only a few years in practice* and am charged therefor £30 sterling. The gold is said to be 18·17 carat and the teeth pin set in ebonite. The upper and lower sets weigh altogether (gold, ebonite, and teeth) nearly two and three-quarter ounces avoirdupois (2¾ oz). Please state if you think the above charge is a fair charge. Also state if you think doctors should expect the services of surgeon-dentists at less than the usual prices charged?

I am, Sirs, yours faithfully,
"MA CONSCIENCE" £30.

*** The opinion sought is a little difficult to give. The fees for artificial dentures differ according to circumstances but we understand that 30 guineas is considered by the best class of practitioners as a good fee. Dental surgeons do not as a rule charge medical practitioners unless the latter desire that a charge should be made and then it is the general practice to charge half the usual fee.—ED. L.

THE ARMY MEDICAL DEPARTMENT OF THE ARGENTINE REPUBLIC.

THE Argentine Republic with a population of 5,190,000 inhabitants maintains a regular army of 1335 officers and 7868 men, but were the reserves to be called out it is said that these numbers would mount up to 8000 and 200,000 respectively. The medical department, which was established by decree in October, 1888, is an autonomous corps under the command of a surgeon-general who has the relative rank of brigadier-general. The number and rank of his subordinate officers are as follows:—Surgeon-colonels, 3; surgeon-lieutenant-colonels, 6; surgeon-majors, 12; surgeon-captains, 12; surgeon-lieutenants, 12; apothecary-major, 1; apothecary-captains, 3; apothecary-lieutenants, 12; apothecary-sub-lieutenants, 18; veterinary-captain, 1; and veterinary-sub-lieutenants, 15. The uniform worn by members of the medical corps resembles that of the infantry of the line, the distinguishing badge being a caduceus encircled by a laurel wreath. Three inconspicuous buttons and button-holes admit of the sleeves being rolled up to the wearer's elbows. In May, 1902, a military medical school was constituted by decree with the object of completing the training of candidates for commissions in the Medical Corps. Students in medicine of two years' standing who have satisfied examiners in zoology, botany, anatomy, and histology are eligible for admission. In the case of postulants who are desirous of serving as apothecaries or veterinary surgeons a single year of preliminary professional study suffices. The school is attached to the military hospital at Buenos Ayres, a very well-appointed establishment with 268 beds. The probationers are subject to military discipline and wear uniform, but although all expenses for food, lodging, clothing, and books are borne by the State a sufficient number of recruits to fill vacancies cannot be obtained. In 1904 there were only 28 medical pupils under instruction, four candidates for the position of apothecary, and eight for that of veterinary surgeon. For the foregoing details we are indebted to an exhaustive article in the *Archives de Médecine et de Pharmacie Militaires* by Surgeon-Major Romary of the French army.

GREEN TEA.

To the Editors of THE LANCET.

SIRS,—Will any of your readers with better opportunities of judging than I have had be kind enough to give their experience of "green" tea as a beverage, saying whether, and, if so, for what reasons, it should be regarded as more or as less wholesome than "black" tea of equally good quality?

I am Sirs, yours faithfully,
Sept. 19th, 1906. G. S. B.

A MOTOR CAR MEDICINE CASE (TABLOID BRAND).

WE have received from Messrs. Burroughs, Wellcome, and Co., of Snow-hill Buildings, Holborn Viaduct, London, E.C., a neat black japanned metal case containing simple remedies and such accessories as will enable first-aid treatment to be administered in the event of certain injuries occurring in a motor-car accident. The case measures 7½ inches by 4¼ inches by 2 inches and is a little over an inch deep. The outfit is thus quite compact and will be useful to the motorist, inasmuch as it will enable him to apply first-aid treatment either in slight or serious cases pending the arrival of the medical man. The contents of the case are varied to meet individual requirements but the stock pattern is fitted out as follows: "Tabloid" pleated dressings comprising one packet of two triangular bandages, one two and a half inches and one one-inch open-wove bandage, one ounce absorbent cotton-wool, and one ounce boric lint. The dressings are compressed and therefore occupy very little space. Then there are one pair of folding scissors, an sponge, two camel hair pencils in glass tube, three yards of half plaster in a tin, court plaster, oiled gauze, safety pins and onll pins. Also there are bottles of carron oil, sal volatile and cast (with brush), and tubes of "borofax" and "protective skin." drugs include tabloid brand products as follows: quinine b gr. 2, soda-mint, cascara sagrada gr. 2, phenacetin compo bismuth salicylate gr. 5, potassium chlorate and borax, and brand products, lead subacetate and boric acid (perfumed for use lotion).

ACETONE COLLODION.

Mr. George M. Beringer has recently communicated a paper to American Pharmaceutical Association (*Chemist and Drug* Sept. 22nd, p. 472) on an improved form of collodion, which prepared by substituting acetone for a mixture of alcohol and as a solvent for the pyroxylin. Acetone possesses remarkable sol properties and is capable of dissolving a wider range of than the official mixture of alcohol and ether. Acetone coll forms an excellent basis for the external application of the phenols, iodine, iodoform, cantharidin, and many other It contains five grammes of pyroxylin and one gramme of made up to 100 cubic centimetres with acetone. A collodion is prepared from powdered cantharides 60 pyroxylin four grammes, camphor one gramme, and suffic acetone to produce 100 cubic centimetres of product. It exert strongly vesicant action. Some of the so-called "liquid court plaster are simply solutions of pyroxylin in acetone.

A SCISSORS SHIELD FOR CIRCUMCISION.

To the Editors of THE LANCET.

SIRS,—My attention has been called to Mr. Haines Cory's clai the originator of the above which he says has been suggested by November, 1900, as a "Frænum Scissors for the Tongue." admitting that there is some resemblance between the two instru I maintain there is a very wide difference, my instrument as unsuitable for cutting the frænum as Mr. Cory's is for circum The chief points between the two are in mine: (1) The groo central and tapers to a fine point with the object of fixing the fo tightly and preventing slipping; (2) the shield and two blades r separate for cleansing purposes; and (3) my instrument is strong larger. Finally, I have never seen Mr. Cory's frænum scissors to-day.

I am, Sirs, yours faithfully,
HENRY DUTCH, M.D. Brux.,
Berkeley-street, W., Sept. 25th, 1906.

◆

G. R.—We doubt whether there is any one book on the histo medicine which will "meet with the requirements of the Lo M.D." Possibly information on the point might be obtained thr inquiry from the Academic Registrar at the University. Our c spondent will find the following books of use: Dr. John Fr "A History of Physick from the Time of Galen to the Sixte Century." First published in 1750. Dr. E. T. Withington, "Med History from the Earliest Times," 1894. Dr. Munk's "Roll of Royal College of Physicians of London" might also be consulted.

X.—A reference to the Medical Directory will show our correspon that there are British practitioners at work in the Argen Republic. For information as to formalities to be complied for leave to practise he is advised to apply to the Consul-General the Republic in this country, Dr. Sergio Garcia Uriburu, 3, Budge-r Cannon-street, London, E.C.

Mr. J. Clarke.—Permission to practise in Monaco is granted foreigners as a favour solely by permission of the Prince of Mon and application should be made to him through the Consul Gene for Monaco in London, Mr. Theodore Lumley, 37, Conduit-str Bond-street, W.

COMMUNICATIONS not noticed in our present issue will receive attenti in our next.
